nent out of state physicians who had distinguished themselves in a field of medicine. Local physicians sometimes supplemented their guest speakers on graduate assembly programs, but conferences generally featured out of state physicians.

Dry clinics and other demonstrations utilizing clinical material have been sponsored in a number of clinical conferences in urban centers, but because of the number of physicians in attendance it was sometimes difficult to keep groups small enough to make clinical observations on patients who were demonstrated. Bedside teaching was rarely attempted for the same reason. Almost without exception, study courses featuring clinical material were designed for practicing physicians.

Some conference programs were arranged according to the needs of the physician who had attended previous conferences. In some states the committee of physicians directing the clinical conference also included physicians active in the state medical society's graduate committee, and in these states duplication of effort and multiplication of graduate activities were avoided.

It has been found difficult to individualize clinical conference programs, particularly for large professional audiences composed of physicians with differing backgrounds and practicing under different circumstances. Physicians from rural areas, for example, might not follow some of the technics employed in highly specialized clinical centers; whereas physicians from urban areas would have difficulty in examining and treating patients under the adverse conditions of rural practice. On this account even within one state it has been necessary to develop more than one general type of program to meet the varying needs of the physicians within the area of the state.

SUMMARY

1. Fifty itinerant courses of continuation study for practicing physicians were offered in or near the home communities of physicians in thirty-eight states during 1938-1939. State medical societies sponsored the majority, with state boards of health as well as extension divisions of universities and medical schools as joint sponsors in many states. Medical schools sponsored most of the fifty-nine opportunities where clinical instruction might be featured at one center over five or more days in twenty-three states and the District of Columbia.

2. A total of forty-three states and the District of Columbia provided a form of continuation study for physicians and, when clinical conferences were included, forty-six states offered graduate opportunities.

3. From 550 to 600 (median) physicians enrolled for continuation study in the states with registration figures. Attendance at clinical conferences varied from 200 to 225 (median). According to reports received, the approximate attendance totaled 37,500 during 1938-1939.

4. One half of the itinerant study courses offered near the home communities of physicians were directed by state medical societies.

5. Pediatrics, obstetrics, medicine, special subjects and surgery were included in the graduate instruction given. Instruction featuring clinical material included laboratory studies in a variety of subjects as well as experience and observation in hospital wards and outpatient clinics.

6. Twenty-six of fifty statewide courses were of five or more days' duration and included symposia, clinics, demonstrations and discussions in hospitals wherever possible. The facilities of medical schools were fre-

quently available for courses emphasizing clinical instruction at one center.

7. Out of state instructors participated as frequently as physicians of the same state; medical schools contributed half of the instructors to itinerant courses and conducted most of the instruction in which clinical material was featured over five or more days.

8. Registration fees were charged infrequently and in no statewide course did amounts exceed \$15. For

graduate programs stressing clinical instruction at one center, larger fees were sometimes required.

9. There were greater opportunities for continuation study featuring clinical instruction than is generally appreciated.

10. Correlation and continuity of the graduate activities of state medical societies and of state boards of health, medical schools, hospitals and other organizations were being accomplished in several states.

RELATED GRADUATE ACTIVITIES

Associated State Committees on Postgraduate Education

At the 1937 annual session of the American Medical Association, the Associated State Committees on Postgraduate Education were organized by Dr. Leroy E. Parkins, Boston, secretary of the Committee on Postgraduate Instruction of the Massachusetts Medical Society. Representatives from thirty-one state society committees attended this initial meeting in Atlantic City. A permanent organization was effected with Dr. James D. Bruce, Ann Arbor, Mich., chairman, Dr. Parkins, secretary, and Dr. Thomas P. Farmer, Syracuse, N. Y., as regional chairman. The associated committees requested official approval of their organization, since it was anticipated that the group would assume some function in the field of graduate medical education. The associated state committees have met each year since 1937 at the time of the annual session of the American Medical Association to discuss recent problems with which state medical societies are concerned. The representatives in this group are actively engaged in graduate teaching and are anxious to receive suggestions from others with related problems.

Representatives from seventeen states were in attendance at the second meeting, held in San Francisco in June 1938. The House of Delegates and the Council on Medical Education and Hospitals of the American Medical Association were represented also. The committee discussed means of providing better medical service to the public by offering practicing physicians in the various states opportunities to learn of recent advances in medicine through a continuous program of graduate instruction. The principal action of this meeting of the committees was a unanimous vote to cooperate with the Council on Medical Education and Hospitals in its present study of continuation courses for practicing physicians in the United States. The associated state committees recommended that all studies in the field of graduate medical education be made in cooperation or collaboration with this Council. It was further recommended that all forms of medical extension courses offered to practicing physicians should be conducted through the offices of state medical societies.

A permanent organization was established and a constitution and by-laws was adopted at the third annual meeting of the associated postgraduate committees, held in St. Louis in May 1939. Under the constitution and by-laws the associated postgraduate committee is defined as a voluntary association of state medical society postgraduate committees and is composed of members of these committees. The officers of this organization consist of a chairman, vice chairman, secretary-treasurer and regional chairmen. At the St. Louis meeting Dr. James D. Bruce was elected permanent chairman, Dr. Thomas P. Farmer vice chairman and Dr. Leroy E. Parkins secretary-treasurer.

A joint exhibit on graduate medical education to be held at the annual session of the American Medical Association was discussed at the last meeting of the committees. It was recommended again that state medical associations be urged to administer continuation courses for practicing physicians, cooperating where desirable with other interested agencies. A report from the Illinois State Medical Society committee was presented at this meeting and the graduate activities in Indiana, Massachusetts, Michigan, Oklahoma and Washington were discussed.

American College of Physicians

In 1938 the Committee on Postgraduate Education of the American College of Physicians, Dr. William J. Kerr, San Francisco, chairman, arranged for two weeks of instruction

immediately preceding the annual session of the college in April. The cooperation of Harvard University Medical School, of Columbia University College of Physicians and Surgeons and of the University of Pennsylvania Graduate School of Medicine was obtained to provide graduate instruction for fellows and associates of the college. Four of the seven courses offered were given, two in Philadelphia in cardiovascular and gastro-enteric disease, one in New York City in general medicine and one in Boston also in general medicine. Registration totaled 117. The college financed promotion, advertising, printing and registration for this program; each school provided faculty and facilities. An appropriation of \$500 was made by the Board of Regents of the American College of Physicians for the graduate instruction given in 1938.

Similar graduate courses were provided during the two weeks preceding the 1939 annual session of the college. Dr. Hugh J. Morgan, Nashville, Tenn., was chairman of the postgraduate committee for this year. Admission to instruction was open to physicians attempting to qualify for membership in the college as well as to members. Two courses were given at Johns Hopkins University School of Medicine and the University of Maryland School of Medicine, Baltimore, one in general medicine and one in cardiovascular and respiratory diseases. Instruction in cardiovascular renal disease was given at Northwestern University Medical School, Chicago, and two courses were given at Washington University School of Medicine, St. Louis, one in cardiovascular disease and one in diseases of the glands of internal secretion. Registration totaled 120. Tuition for the two week courses was \$40 and for the one week courses—given at Washington University—\$20.

In addition to the one and two week review courses given during the past two years under the sponsorship of the American College of Physicians, the college in 1939 granted three research fellowships in the field of medicine. The college is now cooperating with the American Medical Association and with the American Board of Internal Medicine in attempting to elevate standards of medical practice and to encourage graduate medical education. The Board of Governors of the American College of Physicians appointed a committee on postgraduate courses, consisting of five members with Dr. Henry M. Thomas Jr., Baltimore, as chairman for the coming year, to meet the demand for small, personal, specialized courses in the field of internal medicine.

American Academy of Pediatrics

The Committee on Postgraduate Education of the American Academy of Pediatrics, of which Dr. George M. Lyon is chairman, has prepared a suggested outline for the organization of continuation courses for rural physicians. This outline states that in planning a statewide graduate program such factors as the geographic, vocational, economic and population characteristics of the area must be considered. The interest of state medical association committees on maternal and child health and on graduate education and other such committees must be considered also, as well as the possibility of cooperation with the state department of health. Graduate opportunities for practicing physicians in local teaching centers are to be considered as well as opportunities for these physicians to leave for sufficient periods to engage in continuation study elsewhere.

Representation on the committee on maternal and child hygiene or committee on graduate clinical education in the state medical association was emphasized. When advisable, representatives of

special pediatric or obstetric societies should be selected to confer with the state medical association's committee in an advisory capacity. It is of fundamental importance that the committee of the state association be actively engaged in directing the graduate program and be representative.

The academy's committee on postgraduate education states that extension departments of universities may take an active part in developing a medical extension program on a high academic plane. In this connection the importance of a field organizer in stimulating the interest of practicing physicians in each locality is emphasized. Personal interviews by an individual experienced in work of an extension department is helpful.

Typed, personal letters from official representatives of the state medical association explaining the relationship of the medical profession to the graduate courses encourage attendance. Whenever possible, physicians should be urged to sign up for instruction beforehand so that the approximate size of classes in each locality can be determined. The needs of practicing physicians should be noted and catered to whenever possible. The usefulness of printed pamphlets giving specific information as to place, hour of meeting and general outline of course, fees and other notes is emphasized by the committee. Each physician in the district should be sent a prospectus, as well as special letters to those not enrolled for the course.

It is important that local arrangements and details be carefully checked so that no interruptions in the schedule of instruction will occur. An administrative representative from the state medical association should be present at the opening session of each meeting so that the instructor is properly introduced to his professional audience. Technical assistance with movies, lantern slides and other visual aids to instruction are essential. A nurse should be present when clinical material is demonstrated. Whenever suitable, local clinical facilities such as hospitals should be utilized; otherwise, public buildings offer common meeting places.

The academy's outline attempts to insure: (1) an effective program; (2) a program suitable to the physicians of the locality; (3) presentation of stimulating and helpful material; (4) adequate build-up prior to meetings for full attendance and proper appreciation. The technic of promotion is most important and must be better understood and developed to insure success.

Social Security and Other Federal Acts

The provisions of the Social Security Act make no specific stipulation for federal financial participation in supporting graduate medical education. Since February 1936, however, which marks the beginning of social security appropriations, there has occurred certain and often initial participation of various state agencies, under the impetus of federal grants, in the graduate instruction of practicing physicians. Under the present interpretation of the act, graduate teaching may originate locally within each state, may be administered locally under the supervision or approval of the state, with financial participation by the state itself, but must finally be approved by the proper bureaus in Washington before federal funds are allocated. The state agency, usually the health department, must also provide for cooperation with medical, nursing and welfare organizations.

Eight million dollars was appropriated for the fiscal year 1937-1938 for grants in aid to the states for public health work, as authorized under title VI of the Social Security Act. The responsibility of administering grants in aid rests with the United States Public Health Service. During the fiscal year which ended June 30, 1938, \$1,116,000 was allocated to the states for training public health personnel, and 4,300 public health workers were included.

Under a separate act an additional \$3,000,000 was appropriated by Congress for the fiscal year ending June 30, 1939, to assist states in the prevention, control and treatment of venereal disease. The financing of graduate courses for practicing physicians has resulted. During 1938, 422 physicians in fifteen medical and in other centers received instruction in syphilis and gonorrhea.

Appropriations have been made and similar programs have been initiated in various sections of the country by health agencies for other diseases, as cancer, tuberculosis and pneumonia, and in each the instruction of physicians has been considered.

The Children's Bureau of the United States Department of Labor has an annual appropriation of \$3,800,000 for aiding the states in their maternal and child health programs. During the fiscal year which ended June 30, 1938, lecture courses in obstetrics for local practicing physicians were held in 316 centers in thirty-two states. Lecture courses in pediatrics were held in 243 centers in twenty-six states. The bureau also receives \$2,850,000 annually for programs for crippled children. As a result, graduate courses for local physicians in the early recognition and treatment of crippling medical and surgical conditions were provided in seven states.

Lending Library Services for Practicing Physicians

One of the problems with which physicians practicing outside medical centers are faced is the availability of ready reference material to the extensive literature of medicine. It is impossible for physicians to subscribe to all periodicals which must be referred to in case studies. In fact, many medical libraries find it difficult to acquire or have access to the 1,200 or more periodicals, the increasing number of monographs and textbooks on medicine in daily use.

Medical societies and academies of medicine have aided in the establishment of libraries which provide facilities for practicing physicians. Only a few, however, have developed their own complete files of periodicals in sufficient numbers to serve the medical profession adequately. The best known among these are the libraries of the New York Academy of Medicine, the Medical Society of the County of Kings and the Academy of Medicine of Brooklyn, the Boston Medical Library, the Library of the College of Physicians, Philadelphia, and the Library of the Medical Society of the City and County of Denver. State medical libraries have been developed in three states, and state medical associations in other states have begun reprint and periodical libraries for the use of practicing physicians.

The package library service conducted by the American Medical Association has been freely utilized. This service is available to all members of the Association and individual subscribers to any of its publications. Practicing physicians now have lending library services available in thirty states. These include Arizona, California, Colorado, the District of Columbia, Illinois, Indiana, Iowa, Kansas, Kentucky, Louisiana, Maryland, Massachusetts, Michigan, Minnesota, Mississippi, Missouri, Nebraska, New Jersey, New York, Ohio, Pennsylvania, Rhode Island, South Carolina, Tennessee, Texas, Utah, Virginia, Washington, West Virginia and Wisconsin.

While the lending services of medical libraries in the several states have been helpful in supplying physicians with reprints, periodicals, monographs and textbooks, the satisfactory use of such a service depends on the library having two or more copies of material to which frequent reference is made. Whenever this is too expensive to be practical, the Bibliofilm Service of Washington, D. C., can be utilized. Thus, physicians are provided with reference to the complete collections of the Army Medical Library and, by cooperative agreement with this library, the libraries of the United States Department of Agriculture, the Geological Survey and the Bureau of Standards. The use of microfilms is especially helpful in connection with references to pages in bound volumes of considerable value such as incubula and when duplicate volumes are not available.

Graduate Opportunities for Negro Physicians

During the past three years, opportunities for Negro physicians to continue medical instruction have been offered in fourteen states and the District of Columbia. Two medical schools have offered instruction to Negroes, and three other medical schools have opened their facilities to Negro physicians for short courses in general medicine and in such special subjects as syphilis, gonorrhea and tuberculosis. Two Negro universities have provided meeting places for instruction in general medicine and in special subjects. Two hospitals with facilities for colored patients, state boards of health, state tuberculosis associations and two state medical societies have acted as sponsors for courses. States in which continuation study by colored physicians has been offered include Alabama, Georgia, Illinois, Kentucky, Louisiana, Michigan, Mississippi, Missouri, North Carolina, Pennsylvania, South Carolina, Tennessee, Texas and Virginia.

PROGRESS REPORTS BY STATES: 1938-1939¹

Alabama

Realizing the need for a permanent program of organized postgraduate teaching and clinical instruction by representative specialists, the Committee on Postgraduate Study of the Medical Association of the State of Alabama, with the cooperation of the state health officer and the director of the Medical Extension Division of Tulane University of Louisiana, formulated such a plan this year. The association agreed to allocate \$1,000 annually during the next three years; the Commonwealth Fund of New York made a substantial contribution and physicians enrolling for each course were charged a fee of \$5. Selection of subjects and other details of the postgraduate course were considered by the state board of censors, the association's committee on postgraduate study and the director of the medical extension division.

Two out of state medical school instructors were engaged for the first courses in general medicine. Round table discussions and clinical demonstrations were proposed whenever possible. A consultation service was offered to physicians requesting the instructor to see patients when in their community. Courses were arranged on the circuit plan, the state being divided into six circuits, each with five teaching centers. Physicians practicing in every county of the state will have access to these centers. A provision has been made also for the entire series to be given for the Negro physicians of Jefferson County. The field representative of the Division of Medical Extension, Tulane University of Louisiana, makes preliminary arrangements in each locality for the organization and conduct of instruction.

California

The Committee on Postgraduate Activities of the California Medical Association in cooperation with the Bureau of Child Hygiene of the California Department of Public Health engaged an out of state medical school instructor to give a series of postgraduate conferences on maternal care during April and May 1939. Twenty conferences were scheduled in as many localities of the state. In addition the instructor gave lectures at the University of California Medical School, San Francisco, on two days each week. No registration fees were charged.

Connecticut

Five three day courses were offered to practicing physicians who registered this year at the regular assemblies of the Annual Clinical Congress of the Connecticut State Medical Society and Yale University School of Medicine. Comprehensive discussion of each of the following subjects was provided: neuropathology, early treatments of fractures, diagnostic roentgenology, recognition of tumors of the skin, and contraceptive technic. One hundred and forty of the 540 physicians who registered for the clinical congress enrolled in these special courses.

Six postgraduate conferences on clinical problems were given during February and March 1939 at the New Haven Hospital under the auspices of Yale University School of Medicine. Instruction included those aspects of obstetrics and gynecology encountered in the general practice of medicine. Conferences were held to allow physicians to discuss their practical problems. A registration fee of \$10 was charged. Twelve physicians enrolled.

Florida

The Committee on Medical Postgraduate Course of the Florida Medical Association, in addition to sponsoring the annual short course on general subjects of medicine, gave special instruction in diseases of the chest this year. Registration for the special course which was held in conjunction with the

annual graduate short course from June 19 to 24, 1939, was limited to seventeen. An out of state instructor lectured and gave demonstrations on examinations of the chest, fluoroscopy and interpretation of roentgenograms. Five hours of instruction was scheduled for each day. A registration fee of \$5 was charged.

Georgia

The Committee on Postgraduate Medical Education of the Medical Association of Georgia, Dr. G. Lombard Kelly, chairman, recommended in April 1939 that postgraduate medical instruction should be conducted in connection with the two medical schools of the state. The committee believed that such instruction can be more effective in small groups of physicians and that individual instruction should be available to physicians desiring special courses. It was suggested that Atlanta, Augusta, Macon and Savannah might be developed as teaching centers and that it might be desirable to extend postgraduate instruction to the local communities of physicians as well. Financial support of such a program was recommended.

Illinois

The president of the Illinois State Medical Society, Dr. Samuel E. Munson, in his 1939 address stressed the need for the establishment of a plan of postgraduate study for physicians practicing outside the Chicago area. At the last annual meeting Dr. F. G. Norbury introduced a resolution which would provide for a temporary committee of five to study methods of improving postgraduate facilities, especially postgraduate extension courses for Illinois physicians. This committee would report to the house of delegates of the state society at its next annual meeting. The resolution was adopted with the following comments:

The committee on resolutions believes that systematic courses for postgraduate study should be developed under the auspices of the Illinois State Medical Society. Such courses might be given in part in teaching institutions and in part as extension courses in the councilor districts of the state. It is believed that a special committee should study plans operated by other state societies and prepare a program for postgraduate teaching in Illinois. It is suggested that five of the committees having educational functions in the state society and the Department of Public Health of the State of Illinois might be represented on this special committee.

An eight weeks course of lectures, discussions and demonstrations of clinical material in syphilis was begun on April 4, 1939, at the University of Illinois College of Medicine. This instruction was given in two hour periods twice a week by the department of dermatology in cooperation with other departments of the medical college at the Research and Educational Hospital. The course will be repeated four times each year. Registration has been limited to twenty. Licensed practicing physicians were accepted on payment of the registration fee of \$10. The Illinois State Department of Public Health aided in support of the instruction with federal funds. The Clinical Program Committee and Venereal Disease Commission of the Chicago Medical Society began a series of monthly programs which will constitute a symposium on syphilis at the Municipal Hygiene Clinic, Chicago. The first discussion on March 27, 1939, included lectures and presentation of cases of neurosyphilis. Three local consultants participated. No registration fees were charged.

A two day institute for Negro physicians was conducted in April 1939 by the Tuberculosis Institute of Chicago and Cook County. The development, control, detection, prevention and treatment of tuberculosis were considered.

Indiana

Dr. Herman M. Baker, president of the Indiana State Medical Association, in October 1938 emphasized the responsibility of organized medicine for the graduate education of physicians. He cited the need for a full time executive officer to promote the organization and conduct of postgraduate courses in the local communities of practicing physicians. To discharge this responsibility properly it was estimated that it would require about \$12,000 each year and a possible increase in the dues of members of the association. As a preliminary step in a statewide program of postgraduate instruction, it was recom-

1. See Graduate Medical Education: Progress Reports of the Field Study on Graduate Medical Education in the United States Being Conducted by the Council on Medical Education and Hospitals, Organization Section of THE JOURNAL: Arizona, Aug. 5, 1939, p. 514; Arkansas, Feb. 11, 1939, p. 550; District of Columbia, July 15, 1939, p. 237; Louisiana, April 22, 1939, p. 1599; Maryland, July 22, 1939, p. 337; Missouri, Report of Recent Progress, Dec. 17, 1938, p. 2308; New Mexico, Aug. 2, 1939, p. 599; North Dakota, July 15, 1939, p. 237; Oklahoma, March 1939, p. 851; Pennsylvania, April 1, 1939, p. 1262; Texas, Aug. 12, 1939, p. 599; Virginia, Aug. 12, 1939, p. 600; West Virginia, Aug. 5, 1939, p. 514.

mended that five teaching centers be developed in the state similar to the one now being conducted in Muncie by the Delaware-Blackford County Medical Society. The council of the state medical association is giving consideration to these proposals.

The Grant County Medical Society in cooperation with the Committee of Postgraduate Education of the Indiana State Medical Association, the Department of Postgraduate Education of the Indiana University School of Medicine and the Bureau of Maternal and Child Health of the Indiana State Board of Health held a three day postgraduate conference on obstetrics at the Marion General Hospital, Marion. The resident adviser and research director in obstetrics and gynecology at the school of medicine conducted this course. This is the first program of its kind, and it is anticipated that similar efforts will be made in other selected areas of the state. Cases were presented, round table discussions were held and lectures illustrated with movies completed the program. No registration fees were charged.

The Indiana University School of Medicine began in October 1938 two week courses in obstetrics and pediatrics for practicing physicians. The lectures, clinics, symposiums and demonstrations conducted at the medical center were sponsored by the Indiana State Medical Association and the Indiana State Board of Health. Each class was limited to four physicians. Applicants must be recommended by their county medical societies and endorsed by the postgraduate committee of the state medical association. The director of postgraduate education in the medical school is assisted by members of the departments of obstetrics, pediatrics and pathology. Outpatient delivery service, observation in the hospital on the obstetric and pediatric services, conferences and discussions on antepartum and postpartum care, clinics and bedside instruction were included. Clinical pathologic instruction was given daily. Instruction in anatomy of the pelvic region was included. Physicians had an opportunity to witness all abnormal deliveries, attend ward rounds and observe modern medical care.

Iowa

The Council of the Iowa State Medical Society adopted a revised plan of postgraduate education for the state in July 1938. The committee on postgraduate medical education was selected by the councilors so that each councilor district might be represented. This newly formed committee of twenty-eight members conferred with practicing physicians in their respective districts to select the type of postgraduate course desired. In this manner it was possible for the speakers' bureau of the state medical society to present courses planned by the physicians themselves. District and county societies in practically every section of the state have availed themselves of the services of the speakers' bureau.

A study course in the diagnosis of pneumonia was conducted by the director of the state hygienic laboratory in Iowa City over two periods of three days each in December 1938. Twenty physicians registered for this instruction, which was financed with funds from the United States Public Health Service.

Kansas

The Committee on Control of Cancer of the Kansas Medical Society, in cooperation with the Kansas State Board of Health and with financial assistance from the United States Public Health Service, arranged in August 1938 for a course of instruction in cancer in six sections of the state. An out of state speaker was employed during September and again during March 1939, when six other localities were visited. Meetings in each town began at 4 p. m. and continued through 10 p. m. No registration fees were charged.

Kentucky

The chairman of the committee on extension course expressed the belief at the 1938 annual meeting of the Kentucky State Medical Association that other states had found need for conducting postgraduate programs in a systematic way, selecting definite centers where postgraduate meetings might be held. It was emphasized that such a plan could best be carried out in Kentucky by the councilor in each respective district or under the direction of the council of the state association. The

committee recommended that each councilor district have at least two postgraduate meetings each year.

Members of the state association's committee on medical education expressed the opinion that this committee could be made a useful and important part of the association and that it should be made permanent, the members being appointed by the president at the beginning of the year. They also expressed the belief that the *Kentucky Medical Journal* is a most useful source of postgraduate education and that its usefulness in this connection might be extended.

Louisiana

The Flint Goodridge Hospital of Dillard University, New Orleans, in October 1938 began a series of monthly seminars for Negro physicians. Two hours was devoted to discussions by medical school instructors or by members of the hospital staff. Attendance has averaged twenty. No registration fees were charged. Biweekly lectures in tuberculosis and syphilis also began in October 1938. These were under the direction of Dr. John H. Musser, director of the department of medicine. It was estimated that 25 per cent of the physicians of New Orleans registered. No fees were charged.

In addition to the recently developed programs, the hospital has given a two weeks postgraduate course of lectures, demonstrations and clinics in general medicine and surgery each June for four years. Medical school instructors, as well as one or two visiting lecturers, constitute the faculty. Annual attendance has averaged forty physicians, representing approximately one third of the Negro physicians of Louisiana and one fifth of those practicing in the states of Louisiana, Alabama, Arkansas, Mississippi and Texas. A registration fee of \$5 is charged. The administrative cost of these educational programs is provided by a member of the board of trustees of the hospital. Instructors donate their services.

Maine

In November 1938 the county medical society secretaries voted to endorse a proposal whereby the Committee on Graduate Education of the Maine Medical Association would develop a program of instruction to be given at the various county society meetings of the state. This proposal was presented to the house of delegates of the state association in June 1939 and it is anticipated that it will be put into effect in the autumn of 1939.

Massachusetts

The Committee on Postgraduate Instruction of the Massachusetts Medical Society presented the first annual New England Postgraduate Assembly under the auspices of the society during two days of November 1938. Harvard University provided an assembly hall. Ten out of state physicians were guest speakers. General subjects of medicine were discussed. A registration fee of \$3 was charged, which was sufficient to finance the enterprise. Total attendance was 925, physicians coming from each of the New England states and from seven other states.

The committee on postgraduate instruction of the state medical society, with the cooperation of the Massachusetts Department of Health and the United States Public Health Service, began teaching clinics in gonorrhea and syphilis in December 1938 in Boston and in Springfield. Practical instruction in the diagnosis and treatment of these diseases was continued twice a week for twenty-five consecutive weeks.

Michigan

The Executive Committee of the Council of the Michigan State Medical Society complied with the request of the chairman of the advisory committee on postgraduate medical education in October 1938 that the chairmen of the committees on preventive medicine, cancer, radio, maternal health, hygiene and the joint committee on health education be made members ex officio of the postgraduate committee and be urged to attend the meetings of this committee.

The state medical society awarded recognition in September 1938 to those physicians who received graduate instruction sponsored by the society during the past four years. Physicians completing this period of study were designated as associate fellows in graduate education of the state society. Fellowships will be conferred on them on completion of a second similar

term. More than 500 physicians had participated in extramural or intramural courses. The advisory committee on postgraduate medical education had previously established a unit system of credit and determined the minimum requirements for associate fellowships and fellowships in postgraduate education. The first awards of full fellowships will be made this year.

A postgraduate course in pediatrics was given during three days of April 1939 in Detroit. Graduate conferences for physicians were sponsored by the Wayne County Medical Society, the Detroit Department of Health, the Wayne University College of Medicine, the Michigan Branch of the American Academy of Pediatrics, the Michigan Society for Mental Hygiene, Inc., and the Michigan Department of Health. Three Detroit hospitals, the Henry Ford Hospital, the Children's Hospital and the Herman Kiefer Hospital, provided facilities.

Beginning in October 1938 the Michigan Department of Health sponsored at the University of Michigan Medical School, Ann Arbor, two week courses of intensive training and observation in obstetrics and gynecology at the University Hospital. There is a senior instructor in obstetrics in charge, and two practicing physicians may register for this course at one time. No registration fees were charged. Sixty-eight physicians have enrolled to date.

During the spring of 1939 an educational program for Negro physicians was conducted by one of the staff physicians of the Michigan Department of Health. Syphilis was emphasized and both professional and lay instruction was included.

The Wayne County Medical Society, in an effort to expand local educational facilities for physicians, will sponsor graduate courses with Wayne University College of Medicine. In the autumn of 1939 individual instruction at the bedside will be stressed, with the faculty and facilities of the medical college and the City of Detroit Receiving Hospital being available. Groups of not more than six physicians will be enrolled for each session. Weekly ward rounds emphasizing medical diagnosis and treatment will be under the direction of Dr. Gordon Myers, professor of medicine. No registration fees will be charged.

Minnesota

The Minnesota Department of Health, Division of Preventable Diseases, is sponsoring one day of instruction in syphilis and gonorrhea in eight centers of the state during October 1939. The Syphilis Committee of the Minnesota State Medical Association, in consultation with the department of health, selects the subjects for the lectures and round table discussions. Minnesota physicians, chiefly from the University of Minnesota Medical School, will give the instruction, which will be available to all licensed physicians. No registration fees will be charged; the state department of health will finance the course.

Missouri

The Tuberculosis and Health Society of St. Louis, the Mound City Medical Forum and the St. Louis Health Department sponsored a conference for Negro physicians at the Homer G. Phillips Hospital, St. Louis, in April 1939. During the three days of instruction there was general discussion of tuberculosis, syphilis, and child and maternal hygiene.

Montana

The Montana State University, Missoula, and the Montana State Board of Health in the spring of 1939 held a short study course in pneumonia diagnosis. Instruction was available to physicians and laboratory technicians of the state.

New York

Dr. Terry M. Townsend, president of the Medical Society of the State of New York, has emphasized the need of practicing physicians keeping abreast of recent advances in medicine. He has stressed the role of the county medical society in keeping its members informed. Realizing this need, the Onondaga County Medical Society has given a series of courses featuring individual instruction. The outpatient facilities of the Syracuse Free Dispensary were utilized. From three to six sessions were held in each course in medicine, surgery and gynecology. Instructors were chosen from the membership of the county society. Seven courses were offered in the fall of 1938, and from three to five practicing physicians enrolled in each. A

registration fee of \$5 was charged to compensate instructors. The program is a permanent activity of the committee on medical education, with the executive secretary of the county society responsible for circularizing the members to determine their needs.

In April 1939 the New York University College of Medicine gave a series of one hour lectures on syphilis five afternoons a week for eight weeks. These lectures were sponsored in part by the United States Public Health Service. No tuition was charged; a federal grant was obtained to finance the instruction.

North Carolina

Beginning in January 1939 a graduate course in medicine was held at Duke University School of Medicine. Eight out of state lecturers constituted the faculty. Lectures were scheduled for one day each week for six consecutive weeks.

A graduate clinic on the diagnosis and treatment of syphilis was held during two days of March 1939 in Durham under the joint auspices of Duke University School of Medicine and the North Carolina State Board of Health. Seven out of state and five North Carolina physicians participated.

Ohio

The Committee on Education of the Ohio State Medical Association reported the institution of postgraduate lectures in five regions of the state in the past year. Approximately 3,265 members of the association in seventy-seven counties were provided with postgraduate opportunities. The entire cost of this educational activity was met by the state medical association.

A course of eight lectures on various aspects of syphilis was given over a period of eight weeks during February and March 1939 under the auspices of Western Reserve University and the United States Public Health Service. Lectures were held in the auditorium of the library. More than 300 enrolled for this instruction. Members of the university faculty and health officers participated.

During March 1939 the School of Medicine of Western Reserve University and the staff of the City Hospital of Cleveland offered practicing physicians a lecture course on recent advances in medicine, surgery and special subjects. The auditorium of the city hospital was used three days a week. Periods were allowed for discussions following the lectures in obstetrics, gynecology, tuberculosis and other diseases of the chest, diseases of children, diseases of the skin, diseases of the blood, and metabolism.

Oregon

A series of postgraduate lectures in obstetrics and pediatrics was sponsored in May 1939 by the Oregon State Medical Society and the Oregon State Board of Health. Nine sections of the state were included and in each locality the county medical society and the county health department cooperated. Two out of state physicians were engaged. Seven topics in obstetrics and five in pediatrics were available to each group. Meetings usually began at noon and continued until 10 p. m. It is anticipated that this postgraduate activity for practicing physicians will be extended to other subjects of medicine.

Pennsylvania

One week residency courses in obstetrics and pediatrics, under the sponsorship of the state department of health and the Commission on Maternal Welfare of the Medical Society of the State of Pennsylvania, are available to practicing physicians in the state by arrangement through county medical societies. By June 14, 1939, eighty-eight physicians had enrolled. Physicians from outlying sections of Pennsylvania were given the privilege of residing at the Lying-In Hospital, Philadelphia, and at the Elizabeth Steel Magee Hospital, Pittsburgh, where the instruction was provided.

South Dakota

The South Dakota State Medical Association, the University of South Dakota School of Medicine and the state board of health in October and November 1938 provided postgraduate courses for practicing physicians. Obstetrics, pediatrics and syphilis were discussed in the full day meetings which were held

in four sections of the state. Two out of state physicians and two members of the South Dakota State Board of Health gave the instruction. No registration fees were charged.

Tennessee

The Committee on Postgraduate Instruction for the Tennessee State Medical Association sponsored a course in pediatrics, which was organized in the same manner as the one in obstetrics recently completed. Instruction in the first circuit began in February 1939 and included five towns. It is anticipated that the state will be covered in two years. An out of state pediatrician has been engaged and with the assistance of the field organizer will follow the plan previously outlined in obstetrics.

Utah

The second Rocky Mountain Medical Conference will be held in Salt Lake City on Sept. 5, 6 and 7, 1939. This graduate assembly is sponsored by the state medical societies of Colorado, Utah, Wyoming and New Mexico. The facilities of the University of Utah will be at the disposal of the conference. Guest speakers from outside the four cooperating states will conduct the program.

Washington

The recently appointed Committee on Postgraduate Medical Instruction of the Washington State Medical Association has outlined the following plan, which has been approved by the board of trustees of the state association: The committee will direct and supervise postgraduate activities for the practicing physicians of Washington. It will coordinate the activities of the present state association committees as far as graduate medical instruction is concerned. Postgraduate programs will be furnished county medical societies on request. The committee will give an annual postgraduate course of from three to five days' duration designed primarily for the practicing physician. Medicine, surgery and special subjects will be included. Registration fees will be charged to defray the cost of instruction.

Wisconsin

The Council on Scientific Work of the Wisconsin State Medical Society and the Wisconsin State Board of Health presented three one day graduate courses in three centers of the state during April 1939. Five out of state and three Wisconsin physicians participated, with the chairman of the council on

scientific work as general chairman and correlator at each meeting. Postgraduate sessions began at 10 a. m. and continued until 9:30 p. m. each day. Lectures and clinics in medicine, pediatrics, dermatology, gynecology and surgery were available to all licensed physicians. A registration fee of \$5 aided in financing this program. Five hundred and twenty physicians enrolled.

During September 1939 the University of Wisconsin School of Medicine will offer a three day symposium on the blood and blood forming organs. Fifteen out of state physicians will conduct the discussions, which will include round table conferences. The Wisconsin Alumni Research Foundation provided financial support for this program.

Wyoming

The councilors of the Wyoming State Medical Society joined with the state board of health in sponsoring postgraduate instruction for practicing physicians in pediatrics and other subjects. Out of state clinicians were engaged during May and June 1939 to meet with local medical societies and also to provide consultation on request. Ten sections of the state were included in the postgraduate itinerary. In three sections a lecture in orthopedics was given and in one locality obstetrics, gynecology and other medical subjects were included. The instruction was financed by the state health department; no registration fees were charged.

Comment on Recent Progress

There are twenty-two states and the District of Columbia in which the state medical society has organized a committee to correlate and provide for continuity of all or most of the continuation studies of practicing physicians in each state. Included in this group are Alabama, California, Connecticut, Florida, Idaho, Iowa, Massachusetts, Michigan, Mississippi, Nebraska, New Jersey, New York, North Carolina, North Dakota, Ohio, Oklahoma, Pennsylvania, South Dakota, Tennessee, Virginia, West Virginia and Wisconsin.

Nine state medical societies have, within the past year, proposed the formation of such a committee and have recommended appropriate functions for the committee. The states affected include Arizona, Georgia, Illinois, Indiana, Kentucky, Maine, Missouri, Texas and West Virginia. In seventeen other states correlation of continuation studies has not as yet been completely effected.

ESSENTIALS OF AN ACCEPTABLE MEDICAL SCHOOL

(Revised to June 1938)

I. Organization

A medical school should be incorporated as a nonprofit institution. Its board of trustees should be composed of public spirited men or women having no financial interest in the operations of the school or its associated hospitals. The trustees should serve for fairly long and overlapping terms. If the choice of trustees is vested in any other body than the board itself, that fact should be clearly stated. Officers and faculty of the school should be appointed by the board.

II. Administration

There should be careful and intelligent supervision of the entire school by the dean or other executive officer who, by training and experience, is fitted to interpret the prevailing standards in medical education, and who is clothed with sufficient authority to carry them into effect.

There should be a good system of records showing conveniently and in detail the credentials, attendance, grades and accounts of the students, by means of which an exact knowledge can be obtained regarding each student's work. Records should also be kept showing readily the attendance of students at the teaching hospitals and dispensaries and the maternity and post-mortem cases attended.

The school should require that students be in actual attendance within the first week of each annual session and thereafter.

Except for good cause, such as for illness, no credit should be given for any course when the attendance has been less than 80 per cent of the full time.

The school should issue, at least annually, a bulletin setting forth the character of the work which it offers. Such announcement should contain a list of the members of the faculty with their respective qualifications. The courses available should be set forth by departments (anatomy, physiology and so on) showing for each course its number, subject content, character (lecture, recitation, laboratory or clinic), length of time, when, where and by whom given, and the amount of credit allowed. Information should be given regarding entrance requirements and tuition fees. The names of the students enrolled during the current or previous sessions should also be included.

The number of students to whom an adequate medical education can be given by a college is related approximately to the laboratory and hospital facilities available and to the size and qualifications of the teaching staff. A close personal contact between students and members of the teaching staff results in an efficiency which is not possible in an institution where the number of students is excessive.

Advanced standing may be granted to students for work done in other acceptable medical schools, and in granting advanced standing there should be no discrimination against the school's full course students. Official verification of the

student's previous medical work should be obtained by direct correspondence with the school from which he comes, and his preliminary qualifications should also be verified and recorded the same as for freshmen students.

The admission of students to the medical school must be in the hands of a responsible committee or examiner, whose records shall always be open for inspection. Documentary evidence of the student's preliminary education should be obtained and kept on file. When the medical school is an integral part of the university, this work usually devolves on the university examiner. Unless the university examiner and his records are closely accessible, however, some officer at the medical school should obtain and keep on file each student's academic records.

III. Faculty

The school should have a competent teaching staff, graded and organized by departments. Appointments should be based on thorough training, successful teaching experience, ability in research, and willingness to pursue an academic career. In the clinical departments this does not exclude men who are in the active practice of medicine and surgery. Nominations for faculty positions should originate in the faculty, usually being made by the dean in consultation with the department heads or a committee of the faculty. Reasonable security of tenure must be assured in order that the personnel of the faculty may have adequate stability. In the preclinical sciences the faculty should include at least ten qualified persons of professorial rank,¹ devoting their entire time to teaching and to that research without which they cannot well keep up with the rapid progress of medical science. For each twenty-five students in a class there should be at least one full-time assistant in each of the preclinical departments. Salaries should be sufficient to enable members of the faculty to support themselves and their families without the necessity of devoting time and energy to other occupations.

IV. Plant

The school should own, or enjoy the assured use of, modern fireproof buildings sufficient in size to provide lecture rooms, class laboratories, small laboratories for the members of the teaching staff and advanced students, administrative offices and a medical library. Equipment should be adequate, both for student use and for research. A trained librarian should be employed to supervise the operation and development of the library, which should include the more modern text and reference books with the *Quarterly Cumulative Index Medicus*, the *Index Catalogue of the Library of the Surgeon-General's Office* and serviceable card indexes. The library should receive regularly the leading medical periodicals, the current numbers of which should be readily accessible. These periodicals should be bound without delay.

There should be provision for the collection, preservation and indexing of anatomic, embryologic, pathologic and other specimens. With each pathologic specimen coming from post-mortem, the clinical history of the patient on whom the necropsy was held, and microscopic slides showing the minute structure of the disease shown in the gross specimen. The museum furnishes an excellent means of correlating the work of the department of pathology with that of the clinical departments.

There should be sufficient dissecting material to enable each student to dissect at least the lateral half of the human cadaver, to provide cross sections and other material for study and demonstration.

For experimental laboratory work, as well as for medical research, a supply of animals is essential. Proper provision is necessary also for the housing and care of such animals. In any use made of animals every precaution should be taken to prevent suffering, and work by students should be carefully supervised.

Each school should have such useful auxiliary apparatus as stereopticons, reflectoscopes, microprojectors, carefully prepared charts, embryologic or other models, manikins, dummies for use in bandaging, x-ray apparatus, and other aids to effective teaching.

1. Professorial rank as here used includes professors, associate professors and assistant professors.

V. Clinical Facilities

The school may own or control a general hospital. By control is meant the unquestioned right to appoint the attending staff. In this event the students come into close and extended contact with patients under adequate supervision. In the event that a medical school depends for clinical teaching on an independent hospital, it is essential that the clinical teachers, either on nomination by the school or by agreement in conference between school and hospital, be appointed by the hospital trustees to appropriate positions on the hospital staff. Such hospitals should be in close proximity to the school and have a daily average of not less than 200 patients who can be utilized for clinical teaching, these patients to be of such character as to permit the students to see and study the common variety of surgical and medical cases as well as a fair number in each of the so-called specialties. In the use of this material, bedside and ward clinics should be developed for sections of from five to ten students, and patients in medicine, surgery and the specialties should be assigned to each student under a well supervised clinical clerk system. The treatment and care of these patients should be particularly observed and recorded by the student under the strict supervision of the intern, the resident or the attending staff of the hospital. The use of existing municipal or state hospitals for teaching purposes is also advised.

The school should also own or control ample hospital facilities for children's, contagious, and nervous and mental diseases.

The school should own or control a well ordered dispensary or outpatient department with a daily average attendance of at least 100 patients (visits). Good histories and records of the patients should be kept and the material used in medical instruction. The attending staff should be drawn largely from the faculty, including those of highest rank.

At least fifteen maternity cases should be provided for each senior student, who should have actual charge of these cases under the supervision of the clinical instructor. A carefully prepared report of each case should be handed in by the student.

Facilities should be provided for at least fifty necropsies during each school session which are attended and participated in by students. These should be performed by the professor of pathology or a member of his staff. The material thus secured should be used in connection with clinical pathologic conferences.

VI. Resources

Experience has shown that modern medicine cannot be acceptably taught by a school which depends solely on the income from students' fees. No medical school, therefore, should expect to secure approval which does not have a substantial income in addition to students' fees. This statement carries double weight if the school finds it necessary to maintain its own teaching hospital.

VII. Requirements for Admission

1. The minimum requirement for admission to approved medical schools is two years of college training which include English, theoretical and practical courses in physics, biology and general and organic chemistry. Three years or more in college is, however, recommended.

2. Since it cannot in general be assumed that all who have satisfied these requirements merely in terms of hourly credits are fitted for the study of medicine, it is desirable that qualitative standards for admission should be imposed.

3. As a rule candidates should have received their preliminary education in institutions approved by accrediting agencies acceptable to the Council. Exception to this rule may be made in the case of applicants who have demonstrated superior ability. For the convenience of admitting officers the Council has prepared a list of colleges of arts and sciences approved by national and regional educational associations.

4. Admission to approved medical schools may also be by examination under the following conditions:

(a) Candidates who have completed two years of collegiate instruction and present evidence of general scholarship of high order, but who lack credits in not more than two of the required subjects, may be admitted on passing examinations in these subjects.

(b) Candidates who have completed three years of collegiate instruction and present evidence of having accomplished work of distinction in one or more fields of learning, but who lack credit in any or all of the required subjects, may be admitted on passing examinations in these subjects.

VIII. Curriculum

The entire course of four academic years should consist of from 3,600 to 4,400 hours, distributed as from 900 to 1,100 hours a year, and shall be grouped as set forth in the following schedule, each group to be allotted approximately the percentage of hours of the whole number of hours in the courses as stated:

	Per Cent		
1. Anatomy, including embryology and histology...	14	—	18.5
2. Physiology	4.5	—	6
3. Biochemistry	3.5	—	4.5
4. Pathology, bacteriology and immunology.....	10	—	13
5. Pharmacology	4	—	5
6. Hygiene and sanitation.....	3	—	4

	Per Cent		
7. General medicine	20	—	26.5
Neurology and psychiatry			
Pediatrics			
Dermatology and syphilology			
8. General surgery	13	—	17.5
Orthopedic surgery			
Urology			
Ophthalmology			
Otolaryngology			
Roentgenology			
9. Obstetrics and gynecology.....	4	—	5
Totals	76	—	100
Electives	24	—	0

When the teaching conditions demand it, a subject may be transferred from one division to another.

Several of the medical schools now require an internship for graduation. Where it is not obligatory it is strongly urged and graduates should be assisted in securing internships in hospitals approved by the Council on Medical Education and Hospitals of the American Medical Association.

ESSENTIALS IN A HOSPITAL APPROVED FOR TRAINING INTERNS

Revised January 1939

I. Hospitals Eligible for Approval

General hospitals are eligible which admit at least 2,000 patients per year and/or have a daily average census of 75 patients, and which provide a variety of medical, surgical, obstetrical and pediatric patients either in the hospital proper or through suitable affiliations with other institutions. New-born infants are included in computing the daily average census, but are not counted as admissions.

II. The Hospital Staff

1. CHARACTER OF STAFF.—There must be an organized staff of ethical physicians who hold the degree of doctor of medicine from acceptable medical schools; who are of unquestioned professional and moral integrity; who are proficient in general practice or in the special fields to which they devote themselves; who give personal attention to the patients under their charge and who will provide adequate facilities, instruction and that sympathetic cooperation without which interns and graduate students cannot obtain the practical training for which they are serving the hospital.

2. GRADUATES IN MEDICINE.—The hospital must not only confine membership on its staff to reputable practitioners who have received the degree of doctor of medicine from medical schools considered acceptable by the Council on Medical Education and Hospitals of the American Medical Association, but also must apply this ruling to every person permitted to treat or prescribe for the sick in the hospital or in any of its departments. The ruling does not apply to the treatment of patients by nurses, masseurs, and other like assistants, when acting under the orders of any physician on the attending staff.

3. STAFF CONFERENCES.—The hospital staff shall conduct a regular monthly staff conference at which the work of the various hospital departments is considered and where interesting hospital cases and selected autopsy reports may be presented for general discussion. The interns should be expected to attend these meetings and take an active part.

III. Laboratory

1. EQUIPMENT.—There must be a clinical laboratory in the hospital equipped for the ordinary routine tests, and for the more technical bacteriologic, serologic, chemical, basal metabolic, and tissue examinations. A competent physician-pathologist must be in charge of the laboratory, who shall supervise the work in general and personally examine all tissues from the operating rooms and furnish reports of gross or microscopic findings as indicated. Records must be kept in the laboratory of all work carried out by the department, and copies should be filed with the patient's clinical record.

2. AUTOPSIES.—Inasmuch as the per cent of autopsies has come to be recognized as an index of the educational activities in a hospital, no institution will be approved for the training of interns which does not have a record of autopsies of at least 15 per cent. (After Jan. 1, 1940, a minimum of thirty-six necropsies will likewise be required.) The autopsies preferably should be performed in the hospital by or under the supervision of the hospital pathologist who has special knowledge of this type of work and who can furnish reports that include a summary of the clinical record and a detailed description of gross and microscopic findings.

3. AUTOPSY ROOM.—The hospital should provide an autopsy room where postmortem examinations can be held in the presence of staff members and interns.

IV. Department of Radiology

This department must be equipped for at least roentgenographic and roentgenoscopic procedures and must be directed by a physician-roentgenologist who is properly qualified for the work which the department purports to do. Records of the work carried out must be on file in the department, and copies should be filed with the clinical charts.

V. Medical Library

There must be a working medical library, in charge of a librarian, which should contain a useful selection of late editions of standard text and reference books and current files of not less than ten of the better medical journals. The library should be inside the hospital building and be located where it is readily accessible to the interns and staff members. Collections of choice reference books in pathology and clinical diagnosis and in roentgen-ray work should be found respectively in the pathologic and roentgenologic departments.

VI. Histories

1. COMPLETE HISTORIES.—There must be complete histories, giving the patient's complaint, physical examination at time of admission to the hospital, preliminary diagnosis, laboratory findings, description of operation, if any, progress notes, final diagnosis, condition on discharge and, in case of death, autopsy findings if secured.

2. ENDORSEMENT OF HISTORIES.—The histories should show by signatures or initials all persons writing them or parts thereof, as well as the staff members by whom the histories are verified. Likewise, all orders and progress notes should be initialed or signed.

3. RECORDS.—A competent clerk should have charge of the records pertaining to patients. To be of educational value the records must be so handled as to be readily accessible when desired for special study or reference work. There should be

an alphabetical index of patients with cross files according to diagnoses, operations, etc. Lists should also be kept of patients according to departments, i. e., medical, surgical, obstetrical, pediatric, genito-urinary, gynecological, eye, ear, nose and throat, tuberculosis, etc. Hospital days, average daily census, deaths and autopsies should likewise be classified by departments. Histories should be filed so as to be easily accessible. Complete monthly reports and annual summaries should be prepared covering the various hospital departments.

VII. Interns

1. **PURPOSE OF INTERNSHIP.**—It is emphasized that the object of the general internship is to round out the medical graduate's training so as to enable him to enter into the general practice of medicine and not to equip him to enter directly on any specialty. For the latter he should obtain further and different instruction.

2. **TYPE OF INTERNSHIPS.**—The Council approves rotating, mixed and straight internships. A full rotating internship provides training in medicine, surgery, pediatrics, obstetrics and the laboratories. (X-ray and laboratory duties may be combined with clinical services or constitute separate assignments.) A mixed or limited rotating internship covers more than one of the clinical specialties but does not include all of the divisions listed above. A straight internship is an assignment limited to a single department but may include the subspecialties of the same branch. Straight internships are now approved in the divisions of medicine, surgery, pediatrics and pathology.

3. **INTERN SCHEDULE.**—The intern service should cover at least twelve months and should be so arranged as to furnish the interns adequate instruction in medicine, pediatrics, obstetrics, surgery and in the laboratory and x-ray departments. The number of interns should be sufficient to permit each one to study his cases thoroughly. The best institutions employ at least one for each 500 admissions. Accordingly, for a hospital service having 2,000 annual admissions at least three interns will be deemed necessary. The interns should be selected from medical colleges approved by the Council on Medical Education and Hospitals.

4. WORK OF THE INTERNS.

(a) **Histories.**—The interns should personally record a history, a physical examination and their own diagnosis on private and ward patients on their service. The attending physician should in each instance check the intern's work, call attention to errors and supplement the clinical records with any additional findings. The interns in following the progress of the patient should enter progress notes on the chart and the patient's condition on discharge. When a hospital has a shortage of interns a provision should be made whereby the interns on duty may not be burdened by an unreasonable amount of history writing. In such instances it is recommended that a definite number of cases be assigned to the intern and that the other charts be completed by the attending physicians.

It is especially emphasized that surgical charts should be completed promptly and except in emergencies before the patient is taken to the operating room. Unless this is done the educational value of the intern's work is considerably lessened.

(b) **Medical Department.**—This department should afford the interns an adequate amount of instruction in general medicine and pediatrics. Preferably there should also be facilities for the study of tuberculous, neuropsychiatric and contagious patients. In connection with the work in this department it is recommended that the interns be instructed in the feeding of both infants and adults as required in various diseases, and that they obtain a reasonable amount of technical experience under a trained dietitian.

(c) **Obstetrical Department.**—The intern should obtain practical experience in this department by personally delivering at least ten patients while on the service. He should assist at all other deliveries and not act as anesthetist for maternity patients while assigned to this department.

(d) **Surgical Department.**—It should be impressed upon the interns that it is more important for them to acquire skill in diagnosis and postoperative treatment than to learn technical operative procedures. However, in order that the interns may follow their cases closely they should be permitted to act as

first assistant in the operating room whenever possible. To stimulate further interest on the part of the interns, it is also advisable, when an opportunity presents itself, to permit them to perform surgical procedures under constant supervision. Surgical dressings should be assigned to the intern so that he may observe carefully the postoperative course.

The intern should obtain instruction and experience in the administration of the various kinds of anesthetics under the supervision of experienced anesthetists.

(e) **Laboratory Department.**—The intern should have a definite laboratory course wherein he renews his acquaintance with routine examinations and gains instruction from the pathologist regarding the more technical procedures and tissue diagnoses. Interns in the hospital should be present and assist at autopsy procedures when possible, and should receive instruction in technic and in interpretation of findings. Every effort should be made that other assignments may not interfere with the interns' attendance.

(f) **X-Ray Department.**—The roentgenologist should instruct the interns by lectures and demonstrations in the technical, diagnostic and therapeutic use of x-rays.

(g) **Outpatient Department.**—When facilities are available in the outpatient department a regular service should be instituted for the interns if practicable, or else the work in this department should be carried out in conjunction with the respective services in the hospital.

5. **INSTRUCTION OF INTERNS.**—All attending physicians should allow sufficient time at rounds to check the interns' work and to instruct them in connection with their patients. Special attention should be given at this time to dangerously ill patients, and the advice of other physicians on the staff should also be sought.

At least a weekly period should be arranged for conducting clinical-pathological conferences, x-ray lectures or other special lectures or clinics for the interns.

The interns should be encouraged to read medical literature in connection with their patients and should preferably be assigned articles in the medical journals for special study and report.

6. **RECORDS OF INTERNS' WORK.**—State medical examining boards, medical schools and other agencies often desire detailed information regarding the interns' training and, therefore, each hospital should keep a weekly or monthly record of each intern's work. This information is most conveniently supplied to the superintendent or record office by the interns themselves on special forms where space is provided for the following: period covered; service; number of patients admitted on service; number of histories and physical examinations; number of anesthetics given; number of operations assisted at; number performed; number of deliveries attended; number performed; autopsies attended; hours in laboratory; lectures attended; clinics attended, etc.

7. **RULES REGARDING INTERNS.**—The hospital should have a set of printed or written rules and regulations defining the rights, duties and privileges of the interns, a copy of which should be furnished to each intern.

8. **INTERNS' LIVING QUARTERS.**—The hospital shall provide reasonably comfortable living quarters for the interns with opportunities for recreation, both indoor and outdoor, appropriate to the locality and environment of the hospital.

9. **FAITHFUL SERVICE FROM INTERN EXPECTED.**—For all the privileges granted the intern it is understood that the hospital has the right to expect faithful service in return.

The breaking of contracts by interns will be recorded against their standing in the files of the American Medical Association's office unless the interns can show just cause for such action.

VIII. Admission to the Approved List

1. **APPLICATION FOR APPROVAL.**—Hospitals that want to be accredited for intern training should apply to the Council on Medical Education and Hospitals of the American Medical Association, 535 North Dearborn Street, Chicago.

2. **APPLICATION FOR APPROVAL OF INTERNSHIPS.**—Application blanks in duplicate will be supplied on request. These should be filled out carefully by the superintendent or by some staff member who is acquainted with the intern service in the hospital, and one copy returned to the office of the Council.

ESSENTIALS OF APPROVED RESIDENCIES AND FELLOWSHIPS

Residencies and fellowships in the clinical branches of medicine and surgery, pathology and radiology represent advanced training usually in preparation for the practice of a specialty. Residencies in specialties, as defined by the Council, are straight services of one or more years following an approved internship. A fellowship is a form of apprenticeship which in some cases is indistinguishable from a residency, although it usually offers greater opportunity for the study of basic sciences and research. Ordinarily a fellowship is a university rather than a hospital appointment. Mixed residencies are general hospital assignments following internship. (They include services classified as general residencies and chief residencies.)

Approved residencies and fellowships are offered in the following branches of medicine:

- | | |
|--------------------------------|----------------------------------|
| 1. Anesthesiology | 16. Ophthalmology |
| 2. Cardiology | 17. Ophthalmology-Otolaryngology |
| 3. Communicable Diseases | 18. Orthopedic Surgery |
| 4. Dermatology and Syphilology | 19. Otolaryngology |
| 5. Epilepsy | 20. Pathology |
| 6. Fractures | 21. Pediatrics |
| 7. Gynecology | 22. Physical Therapy |
| 8. Malignant Diseases | 23. Plastic Surgery |
| 9. Medicine | 24. Psychiatry |
| 10. Mental Deficiencies | 25. Radiology |
| 11. Mixed Residency | 26. Surgery |
| 12. Neurology | 27. Thoracic Surgery |
| 13. Neurosurgery | 28. Traumatic Surgery |
| 14. Obstetrics | 29. Tuberculosis |
| 15. Obstetrics-Gynecology | 30. Urology |

I. General Requirements

Registration.—Previous admission to the Register of the American Medical Association is essential in the case of hospitals offering fellowships and residencies in specialties.

This implies that each hospital must be adequately organized, staffed and equipped and that it be conducted primarily for the welfare of the sick. The educational function described in these Essentials is supplementary to the main purpose of the hospital service but is closely related thereto in that it serves to improve the quality of medical practice.

Size.—The size of the institution is not a primary consideration. The clinical material, however, should be sufficient to enable residents and fellows to observe the principal manifestations of the disease, or diseases, they are studying.

Plant and Equipment.—The physical plant should be such as to assure the safety and comfort of the patients. There should be such equipment, appliances and apparatus as are commonly employed in the specialty in which training is offered and in the use of which the resident should become proficient.

II. Staff

There must be an organized staff of ethical, licensed physicians holding the degree of doctor of medicine from acceptable medical schools. The particular specialties in which residents are being trained must be represented on the staff by well qualified, experienced and proficient physicians.

In general hospitals, the staff shall further provide a definite departmental organization in those branches of medicine in which residencies are offered. The director of each service should be a competent specialist who is at least eligible for certification by the corresponding specialty board. He should assume direct responsibility for the training of residents and fellows and should stimulate others of his staff to give instruction and sympathetic cooperation which graduate students require.

It is essential that there shall be at least monthly clinical-pathologic conferences or other regular staff meetings at which histories and clinical observations in selected cases may be reviewed, particularly when the death of patients has necessitated special study including necropsy performance. In addition to meetings of the staff as a whole, it is expected that departmental conferences shall be conducted in which residents may take an active part to the end that the character of the service given by that department to its patients may be recurrently evaluated. Other educational activities requiring the full support of the staff are described under Training Program, section IX.

III. Department of Radiology

The department of radiology shall be under the direction of a qualified radiologist proficient in the various functions of his specialty. He must likewise cooperate in all matters pertaining to residencies and fellowships which fall within the scope of his service. The department should contain roentgenographic, roentgenoscopic and, where required, therapeutic equipment and radium. All these facilities are essential in institutions offering a complete residency or fellowship program in radiology.

After Jan. 1, 1942, an applicant for certification by the American Board must have completed a period of study after the internship of at least three years in a recognized institution or radiologic department. This period of specialized training should include an active experience in radiology of not less than twenty-four months and graduate instruction in pathologic anatomy, radiophysics and radiobiology. Board certificates are offered in (1) the entire field of radiology, (2) roentgenology, (3) diagnostic roentgenology and (4) therapeutic radiology.

Residencies and fellowships of from one to three years' duration should be organized in such a manner that on completion of the graduate program the aggregate of training will coincide with the foregoing requirements. Courses of shorter duration, however, may provide the basic instruction in radiology required by other specialties. A complete residency or fellowship program supplies training in all divisions of the specialty—diagnostic roentgenology, therapeutic roentgenology and radium therapy. Without attempting to define a detailed plan of instruction it can be suggested that the first year be devoted principally to pathology, roentgenologic technic and a general orientation in the radiologic field. In the second and third years the clinical applications of radiology should be emphasized with at least six months assigned exclusively to radiotherapy. In view of the importance of pathology as a basis for radiologic diagnosis and therapy it is recommended that a minimum of six months be devoted to pathologic anatomy, particularly the study of gross pathology and tumors. Instruction in radiophysics and radiobiology may well run concurrently with the training in radium therapy and therapeutic roentgenology.

Residencies in a restricted field of radiology can likewise be modeled on this plan. The training should be systematic and progressive in character with gradual assignment of responsibility in both diagnosis and therapy. It should also include an active participation in radiologic conferences, staff meetings, and joint conferences with other departments. An adequate amount of clinical material must be available in the divisions of radiology in which residency or fellowship training is offered.

IV. Department of Pathology

The department of pathology must be under the supervision of a qualified pathologist who shall be prepared to cooperate fully in the training of graduate students and supervise any direct contact which they have with the laboratory. The department should provide apparatus, reagents and materials necessary to the operation of a modern clinical and pathologic laboratory. Adequate necropsy facilities should also be available.

Residencies and fellowships, in contrast to the shorter courses for basic instruction in pathology, are ordinarily of from one to three years' duration. Thus they may serve to fulfil the requirements for certification, which specify in addition to the internship a period of study of at least three calendar years, including one year in the various phases of clinical pathology and not less than two years of training and experience in a department of pathologic anatomy. (The training may be combined or in sequence.)

The teaching material must be sufficient in kind and amount to afford graduate students adequate training in all divisions of the service and in both gross and microscopic pathology. Systematic instruction should be carried out with the use of fresh material and collections of slides and museum specimens for comparative studies in histology and pathology. As the training continues an increasing amount of responsibility should be assigned to the residents and fellows in tissue diagnosis, in actual performance of postmortem examinations and in the preparation of pathologic reports and necropsy protocols.

Further instruction should be obtained through active participation in clinical-pathologic conferences, staff meetings and joint conferences with other departments.

V. Necropsies

Thoroughness in postmortem performance should be emphasized. All institutions and individual clinical services desiring approval for the training of residents or fellows must examine post mortem 15 per cent or more of their fatal cases. An additional requirement of at least 100 necropsies a year applies to institutions offering residencies or fellowships in pathology. Complete necropsy records should be kept on file and each should contain a summary of the clinical record and a detailed description of both the gross and the microscopic observations. Graduate students of all departments should attend postmortem examinations as often as possible. They may, with value, participate in the performance of necropsies from their own service and in the preparation of the protocols.

VI. Medical Library

Institutions offering graduate training should maintain or provide ready access to an adequate medical library containing modern texts, the *QUARTERLY CUMULATIVE INDEX MEDICUS* and current journals relating to the fields in which residencies and fellowships are offered.

VII. Histories and Records

There must be complete histories giving the patient's complaint, physical examination at time of admission, preliminary diagnosis, laboratory observations, descriptions of operations if any, regular progress notes, final diagnosis, condition on discharge, end results and, in case of death, necropsy observations if postmortem examination is performed.

The histories should show by signatures, or initials, all persons writing them or parts of them as well as the staff members by whom the histories are verified. Likewise, all orders and progress notes should be initialed or signed.

The records should be in charge of some competent person, preferably a trained record librarian. Alphabetical and diagnostic indexes of the patients should be maintained and the records filed so as to be readily accessible from either source. Operative procedures and radiologic and pathologic material should likewise be classified in a suitable manner.

VIII. Eligibility of Applicants

Candidates for residencies or fellowships should be selected from graduates of approved medical schools, who have served an internship in an approved hospital or have had two or more years in practice. It is recommended, however, that candidates seeking residencies or fellowships in such specialties as urology, orthopedics, plastic surgery, thoracic surgery and neurosurgery should have completed one year of general surgical training in addition to the internship.

IX. Training Program

Residencies and fellowships are designed primarily to meet the requirements for certification of special practice. Individually they may not fulfil all the essentials of a specialty board, but each service that is properly organized will make a substantial contribution to the graduate program. In all instances the term of service should be at least twelve months and might well be extended to two or more years when suitable facilities are available. An affiliation with a university or medical school is desirable to provide the required training in basic sciences relating to individual specialties.

Aside from the daily contact with patients and staff men, the assumption of responsibility is the most valuable aspect of residency and fellowship training. Consequently, as ability is demonstrated, an increasing amount of reliance should be placed in the judgment of graduate students both in diagnosis and in treatment.

Residents and fellows should be given an opportunity to contribute to the effectiveness of the hospital service by some investigative work. This may take the form of research in the hospital laboratories or wards, summaries of medical literature, or the preparation of statistical analyses derived from the hospital record department. The members of the resident staff

should likewise be encouraged to engage in teaching activities, particularly in relation to the training of medical students, interns and nurses.

The effectiveness of a residency or fellowship program depends largely on the quality of medical supervision and teaching. It is important, therefore, that methods of instruction be employed which are best suited to the special field. Emphasis should be placed on bedside instruction, teaching rounds, departmental meetings or seminars, clinical-pathologic conferences, demonstrations and lectures. The review of medical literature is an essential feature of residency training. Likewise the study of basic sciences as required by specialty boards should be integrated with the clinical experience. In the operative divisions it is desirable that facilities be available for anatomic dissection and experimental surgery on animals or on the cadaver. Additional requirements apply to graduate courses leading to advanced degrees.

The following regulations pertaining to individual specialties contain a brief abstract of the special training required for certification by the Specialty Boards. The full requirements for certification should be ascertained by direct correspondence with the secretary of each board as listed in section XI.

1. **Anesthesiology.**—Present requirements for certification by the American Board include an internship of one year and at least four calendar years of active experience limited to anesthesiology. This period of specialized training and practice should include a minimum of two years of supervised clinical instruction in anesthesiology and graduate study in the related basic sciences, particularly anatomy, physiology, pharmacology and biochemistry. After Jan. 1, 1942, the requirements will be interpreted as three years of special training and three years of additional practice in anesthesiology.

The director of the department should be a qualified physician limiting his practice to anesthesiology. It is preferable that he serve on a full time basis to supervise the technical and educational activities of the department. His staff must include an adequate number of trained anesthetists in accordance with the needs of the service.

Equipment must be satisfactory for the teaching of modern methods of anesthesia and should include suitable apparatus for gas administration, resuscitation and inhalation therapy. Likewise, the clinical material must be sufficient to afford graduate students adequate experience in the various methods and types of anesthesia now commonly employed. It is expected that each graduate student should administer a minimum of 500 anesthetics a year, of which 400 should be general surgical in type. Residencies and fellowships organized in accordance with the foregoing requirements should provide systematic clinical and technical instruction supplemented by seminars, lectures and demonstrations on anatomic and other material.

2. **Cardiology.**—(See Medicine.)

3. **Communicable Diseases.**—(See Medicine.)

4. **Dermatology and Syphilology.**—In order to qualify for certification in dermatology and syphilology, graduate students who begin their training after Jan. 1, 1940, must complete three years of systematic instruction and two additional years of study or practice. The period of specialized training following internship shall include (a) not less than eighteen months of active experience in clinical dermatology and syphilology and (b) graduate study in the basic sciences of embryology, histology, chemistry, physiology, bacteriology, mycology, parasitology, pathology, immunology, serology, pharmacology and physics as related to physical therapy.

Residencies and fellowships designed to meet these requirements should provide an organized course of instruction involving lectures, seminars, clinical demonstrations and laboratory assignments, especially in histopathology, parasitology, mycology and immunology. To facilitate clinical and laboratory teaching it is essential that the department have ready access to an adequate supply of classified anatomic and pathologic material including histologic and lantern slides for demonstrations. Projection apparatus should be available and also facilities for clinical photography.

Since the practice of dermatology and syphilology is concerned largely with ambulatory patients, it is essential that an active outpatient service be available to furnish sufficient clinical

material in the various subdivisions of the specialty. It is also desirable that hospital facilities be available and that graduate students be given an opportunity to observe the dermatologic manifestations of the acute contagious diseases. Ordinarily a minimum of 3,500 annual visits is considered essential in the dermatologic division and a similar number in syphilology.

5. **Epilepsy.**—(See Psychiatry and Neurology.)

6. **Fractures.**—(See Surgery; also Orthopedics.)

7. **Gynecology.**—(See Obstetrics and Gynecology.)

8. **Malignant Diseases.**—The division of malignant diseases is largely a combination of services involving practically all the branches of medicine and surgery, including pathology and radiology. It is important, therefore, that competent staff physicians be assigned to all departments and that special facilities be available for histopathology, diagnostic roentgenology, operative surgery, therapeutic roentgenology and radium therapy.

The clinical material should be sufficient in kind and amount to enable graduate students to observe and study the various types of malignant diseases and the methods of therapy commonly employed. A teaching service should have approximately 350 inpatients a year and additional material in the outpatient tumor clinic.

Ordinarily, the training is general in type with assignments in clinical diagnosis, pathology, diagnostic roentgenology, surgery, therapeutic roentgenology and radium therapy. Courses in surgical and postmortem pathology, radiophysics and radiobiology are often included. In some instances the service is limited in scope and is utilized primarily as supplementary training in internal medicine, surgery, pathology, radiology or other specialties.

9. **Medicine.**—Requirements for certification in this specialty include an approved internship of at least twelve months, three years of special training and two additional years of practice in the field of internal medicine or its more restricted and specialized branches. The graduate training should include several months of properly supervised instruction in anatomy, physiology, biochemistry, pathology, bacteriology or pharmacology as related to medical specialties.

Residencies and fellowships should necessarily be organized on a broad basis to furnish instruction in the various specialties which combine to form the foundation of practice in internal medicine. Accordingly, the service should not be limited entirely to general medicine and its subdivisions of allergy, cardiology, gastro-enterology, metabolic diseases, contagion and tuberculosis but might well include a reasonable amount of instruction in the divisions of psychiatry and neurology, dermatology and syphilology, and pediatrics, now organized as independent specialties.

It should be taken into account, however, that not more than one year of instruction in the related medical specialties and basic sciences can be applied to the three year period of special training.

In institutions offering residencies and fellowships in general medicine, cardiology, communicable diseases or tuberculosis, emphasis should be placed on the educational features of the service and residents should receive regular instruction from members of the staff in methods of clinical study and diagnostic and therapeutic procedures. Of particular importance is the study of etiology, pathogenesis, symptomatology and course of the various diseases so that the residents may develop skill and accuracy in diagnosis as well as a mature judgment and resourcefulness in therapy.

Under the supervision of qualified members of the staff the residents should assume individual responsibility in actual case management. They should also be required to correlate clinical studies with postmortem pathology, review medical literature and take an active part in weekly teaching rounds, departmental seminars and clinical-pathologic conferences. Instruction in the basic sciences may well be integrated with the clinical experience.

Training in tuberculosis should be of such a character that residents may become thoroughly familiar with the various phases of institutional service as well as the community aspects of tuberculosis control. This necessitates a well organized program of instruction with rotating assignments in the admitting department, infirmaries, convalescent and ambulatory wards and the outpatient clinics. Careful instruction should be provided

in diagnosis, interpretation of roentgenograms, therapeutic procedures and general sanatorium care. It is particularly important that the residents become fully acquainted with the use of pneumothorax therapy and the technic of the initial induction as well as the subsequent refills. If a surgical department is maintained, the operative service may be combined with the general training in tuberculosis or it may form the basis of a separate residency in thoracic surgery.

It must be emphasized that residencies in tuberculosis are educational in character and that of the full time sanatorium staff only those physicians who serve primarily on an educational basis come within the residency classification of the Council.

The clinical material must be adequate in kind and amount. In general medicine a minimum of 400 annual admissions is considered desirable, while in tuberculosis approximately 125 inpatients a year may be sufficient.

Residencies in cardiology and communicable diseases may well follow the general plan indicated. In cardiology a large part of the required teaching material is frequently supplied on a consultation basis and therefore the number of patients admitted directly to the department may not be an accurate index of the scope of the service. A well balanced service is essential for residency training in contagious diseases. Between 300 and 400 admissions a year may be considered sufficient, especially if most of the acute contagious diseases are well represented.

10. **Mental Deficiencies.**—(See Psychiatry and Neurology.)

11. **Mixed Residency** (see definition in opening paragraph).

All hospitals approved for intern training are automatically accredited for mixed residencies which represent general assignments of at least one year duration following an approved internship. Other hospitals presenting a general service and an admission rate of at least 1,500 patients a year may likewise be certified if they conform to the general requirements for residency training.

12. **Neurology.**—(See Psychiatry and Neurology.)

13. **Neurosurgery.**—(See Surgery; also Psychiatry and Neurology.)

14. **Obstetrics.**—(See Obstetrics and Gynecology.)

15. **Obstetrics and Gynecology.**—Candidates for certification in obstetrics and/or gynecology must in addition to other requirements have completed a year of internship and five years of practice including at least three years of special training in obstetrics and/or gynecology. After Jan. 1, 1942, the requirements for all candidates will consist of one year of approved internship followed by a minimum of seven years of practice including not less than three years of special training in obstetrics and/or gynecology.

Institutions offering residencies or fellowships in obstetrics and/or gynecology must provide surgical and obstetric facilities adequate for the clinical and teaching needs of the service. They should also furnish sufficient teaching material to afford graduate students a wide experience in clinical diagnosis, treatment, and technical and operative procedures. Ordinarily an admission rate of 400 patients a year is considered necessary for graduate training in obstetrics and a similar requirement applies to gynecology. In a combined service each division should furnish a corresponding amount of clinical material. Antepartum and follow-up clinics are also essential.

The graduate program should include the study of fundamental subjects, particularly obstetric and gynecologic pathology, anatomy, embryology and physiology. Primarily, however, the emphasis should be placed on clinical training in order that graduate students may receive ample instruction in the various phases of gynecologic and obstetric service—antepartum care, treatment of toxemias of pregnancy, management of normal and abnormal labor, technic of versions, breech extractions and instrumental delivery; diagnosis and treatment of the complications of labor, postpartum hemorrhage, puerperal infections; operative obstetrics and gynecology. Courses of instruction should include assignments in pathology, demonstrations on the manikin, departmental seminars, clinical-pathologic conferences, and teaching rounds. Training in surgical technic should be sufficient to enable residents and fellows to undertake operative work on their own responsibility especially toward the end of the graduate program.

16. Ophthalmology.—To become certified in ophthalmology a candidate must have completed an internship of one year or its equivalent and a period of combined study, training and practice of not less than three years. The special training should include active clinical experience and graduate study of related basic sciences, particularly anatomy, histology, embryology, optics, physiologic optics, visual physiology and psychology, pathology, bacteriology and pharmacology. The candidate should have knowledge of the application of these subjects and their use in clinical ophthalmology especially in refraction, disorders of motility and binocular vision, perimetry, and in the use of the ophthalmoscope, retinoscope and slit lamp.

Residencies and fellowships should be organized in such a manner that on completion of the graduate program the aggregate of training should coincide with the foregoing requirements. There must be adequate equipment for diagnosis, therapy, refraction, operative procedures, and preferably additional facilities for dissection and experimental surgery. Histologic and pathologic material should be available for demonstration and individual study. The clinical facilities must be sufficient in kind and amount to afford graduate students an adequate experience in diagnosis, therapy and operative technic. Ordinarily a minimum of 150 admissions and 1,500 outpatient visits a year is considered necessary for graduate training in this specialty.

A systematic course of instruction should be offered with regular lectures and demonstrations in clinical and operative ophthalmology. Instruction in surgical technic should be sufficient to enable residents and fellows to undertake operative work on their own responsibility, especially toward the end of the graduate program.

17. Ophthalmology-Otolaryngology.—A joint service in ophthalmology and otolaryngology should fulfil the requirements listed under each department except that five years of training and experience should constitute the minimum time required.

18. Orthopedic Surgery.—After Jan. 1, 1940, candidates for certification must have completed one year of internship, three years of concentrated instruction in orthopedic surgery and two years of subsequent practice in this special field. Knowledge of the basic sciences related to orthopedic surgery is also required.

As preliminary training the Council recommends one year of general surgery in addition to the internship. Surgical and orthopedic facilities must be satisfactory and clinical material sufficient to afford graduate students adequate experience in the correction of congenital and acquired deformities and in the treatment of fractures and other acute and chronic disorders which interfere with the proper function of the skeletal system and its associated structures.

Both hospital and outpatient facilities are desirable, and institutions offering graduate instruction should treat a minimum of 200 patients annually. Students should become thoroughly familiar with all methods of diagnosis and treatment, corrective exercises, physical therapy, operative procedures and the use of orthopedic appliances. Instruction in surgical technic should be sufficient to enable residents and fellows to undertake operative work on their own responsibility, especially toward the end of the graduate program.

Graduate study is recommended in the fundamental sciences of anatomy, embryology, physiology, pathology, bacteriology and biochemistry. Clinical instruction should include teaching rounds and departmental conferences.

19. Otolaryngology.—The qualifications for special practice in this field include an approved internship and three years of graduate preparation, with at least one and preferably two years in recognized residencies or basic courses followed by private practice in otolaryngology.

Residencies and fellowships in otolaryngology should aim to provide adequate clinical and operative experience and additional opportunities, if possible, for graduate study in the related basic sciences of anatomy, embryology, histology, physiology, pathology, bacteriology and pharmacology.

Essential equipment for diagnosis and surgery should be available, including an audiometer and other special apparatus depending on the scope of the service. The department should further provide histologic and pathologic material for demonstrations and study and preferably facilities for experimental

surgery and dissection of the head and neck. The clinical material should be sufficient in variety and amount to provide adequate training in the various divisions of the service, which might advantageously include the field of bronchoscopy. It is generally assumed that a graduate service would require a minimum of 400 admissions a year and at least 3,500 visits in the outpatient department.

The training should include a systematic course of instruction with lectures and demonstrations on clinical and technical subjects pertaining to the various phases of otolaryngology. Instruction in surgical technic should be sufficient to enable residents and fellows to undertake operative work on their own responsibility, especially toward the end of the graduate program.

20. Pathology.—(See Department of Pathology, section IV.)

21. Pediatrics.—To qualify for certification in pediatrics a candidate must have completed five years of training and practice after graduation from an approved medical school. The requirements include an approved internship of one year, a service of two years in a pediatric center and two additional years of specialized study or practice. Although the training need not be continuous or in the same institution, it is desirable that the educational program be systematized in the form of residencies or fellowships of from one to three years' duration.

Clinical training should be obtained in general medical pediatrics, nutritional disorders, care of newborn infants, preventive pediatrics and outpatient clinics in the various departments of medical pediatrics. Correlative studies are recommended especially in contagion, well baby clinics, mental deficiencies, neurologic disorders of children and behavior problems. Sufficient time should also be devoted to the fundamental subjects of physiology, embryology, nutrition, growth and development.

In the wards and in the clinics the residents and fellows should be permitted to assume individual responsibility in diagnostic and therapeutic procedures and case management. They should actively participate in teaching rounds, clinical-pathologic conferences, departmental seminars and all other functions designed to improve the quality of the clinical and educational service. To supply an adequate amount and variety of teaching material a department should provide a minimum of approximately 200 annual admissions in general medical pediatrics.

22. Physical Therapy.—The department should be under the direction of a physician qualified by training and experience in physical therapy. He should spend sufficient time in the department daily to supervise actually the work of the graduate students and technicians. Adequate space and apparatus should be furnished in the department for all phases of the work. The clinical material should be sufficient in kind and amount to enable the residents and fellows to observe and study all forms of treatment in physical therapy. Both inpatient and outpatient clinical material should be available.

The training should include (a) the study of certain fundamental subjects: physics of light, heat, electricity and mechanics; anatomy, with special reference to the peripheral nervous system, muscles, blood vessels, bones and joints, physical chemistry as related to physical therapy; physiology; (b) clinical and hospital training in the study and treatment of patients by various physical agents—light therapy, thermotherapy, fever therapy, hydrotherapy, electrotherapy and mechanotherapy. Emphasis should be placed on subjects related to physical therapy such as orthopedics, neurology, roentgenology, dermatology and general medicine.

A minimum of three years of special training is considered necessary for a physician to qualify as a specialist in physical therapy.

23. Plastic Surgery.—(See Surgery.)

24. Psychiatry and Neurology.—Specialized training and experience of at least five years is essential for certification in neurology or in psychiatry. (To qualify in both fields a minimum of six years is required.) The requisite training consists of three full years of study after the general internship, and two or three additional years of practice or study in psychiatry or neurology or both. During the period of training a program of graduate studies should run concurrently with clinical instruction, covering the fundamentals of neuroanatomy, neuropathology, neurophysiology, psychobiology and psychopathology.

In institutions offering residencies and fellowships of from one to three years' duration, emphasis should be placed on the educational features of the service, and the residents should receive regular instruction from members of the staff in general orientation in the specialty, and diagnostic and therapeutic procedures and methods of clinical study as well as in the organization of ward services. Administrative details, progress notes, and contact with patients' relatives should be kept sufficiently within bounds so that the residents may employ their time in the study and treatment of neurologic and psychiatric disorders. Emphasis should be placed on the study of etiology, pathogenesis, symptomatology and course of the various diseases so that the residents may develop skill and accuracy in diagnosis, as well as mature judgment based on knowledge of the natural history of the diseases and resourcefulness in therapy.

A rotating assignment in psychiatry is essential to give residents adequate experience on the admission services, on the infirmaries and wards, in the therapeutic divisions and in the outpatient clinics. A resident in neurology should have adequate contacts with psychopathic departments, general medicine, pediatrics, contagious disease and tuberculosis services so that he may become familiar with neurologic complications of general diseases, and he should also witness or assist at whatever neurosurgical operations are performed in the hospital. Teaching rounds, clinical and pathologic conferences and seminars are essential for clinical instruction in both fields.

The clinical material must be adequate in kind and amount. Between 200 and 400 admissions a year per resident is considered desirable. Smaller numbers prevent proper survey of the field of neuropsychiatric disorders; larger numbers are incompatible with adequate study of the patients admitted. Similar requirements apply in institutions where separate residencies are offered in the field of epilepsy and mental deficiencies, except that not more than one year of residency in either type of hospital will be considered as preparation for the specialty of psychiatry or neurology. It must be emphasized that residencies in psychiatric and neurologic hospitals are educational in character and that, of the full time psychiatric or neurologic staff of such hospitals, only those physicians who serve primarily on an educational basis come within the residency classification of the Council.

25. Radiology.—(See Department of Radiology, section III.)

26. Surgery.—The requirements for certification by the American Board of Surgery include an approved internship and at least five additional years of special training in surgery. During this period the entire time should be devoted to surgical training supplemented by sufficient experience in the basic sciences of anatomy, physiology, pathology, bacteriology and biochemistry.

Residencies and fellowships organized in accordance with these requirements may be from one to five years' duration but need not necessarily be confined to one institution. In aggregate, however, the training should coincide with the plan described. Individual residencies may be conducted in general surgery, fractures, neurosurgery, plastic surgery, thoracic surgery, traumatic surgery and other surgical divisions now organized as independent specialties. As preliminary training for residencies and fellowships in such specialties as neurosurgery, orthopedics, plastic surgery, thoracic surgery and urology the Council recommends one year of general surgery in addition to the internship.

All surgical departments can readily subscribe to the same general plan of training, although their scope of service may show considerable variation. Training in most of the surgical specialties is ordinarily limited to one division, but residencies in general surgery may well encompass the entire surgical field with the possible exception of ophthalmology and otolaryngology.

It is essential that adequate supervision be maintained by a competent department head responsible for the organization of the graduate program. He should personally direct the plan of clinical and operative training but may well rely on qualified assistants to supervise certain details of the educational service. Residencies and fellowships should emphasize careful training in diagnosis, preoperative therapy and postoperative care. This requires systematic bedside instruction, correlation of clinical and operative data, the study of gross and microscopic pathology,

collateral reading, and accurate observations throughout the entire course of the disease. Supplementary instruction should be furnished in the form of departmental seminars, teaching rounds and clinical-pathologic conferences, usually on a weekly basis. It is also desirable that facilities be available for anatomic dissection and experimental surgery on animals or on the cadaver. Surgical training should be obtained under the careful guidance and supervision of competent specialists. It should be sufficient in amount to insure a reasonable degree of technical proficiency and thus enable the residents and fellows to undertake operative work on their own responsibility, especially toward the end of the graduate program.

Equipment and facilities for general and special surgery must be adequate to meet the needs of the service. The clinical material should likewise be sufficient to furnish adequate experience and training in diagnosis, therapy and operative technic. Accordingly it is suggested that general surgical services provide approximately 400 annual admissions per resident. The same amount may not be necessary for separate residencies in fractures, neurosurgery, plastic surgery, thoracic surgery and traumatic surgery, but even in the most limited of these specialties there should be at least 150 patients treated annually.

27. Thoracic Surgery.—(See Surgery; also Tuberculosis.)

28. Traumatic Surgery.—(See Surgery.)

29. Tuberculosis.—(See Medicine.)

30. Urology.—For certification in urology a minimum of five years of special training and practice is required after the internship. This period of preparation should include an active clinical experience of at least eighteen months, graduate training in anatomy, physiology, pathology and other basic sciences, and not less than two years of additional practice.

As preliminary training for residencies and fellowships in urology, the Council recommends one year of general surgery in addition to the internship. Graduate instruction should be organized in accordance with the aforementioned requirements. It should be systematic and progressive in character to the end that adequate training may be obtained in diagnosis, therapy, cystoscopic examinations, pyelography and operative procedures, all under the supervision of a well qualified urologist.

Instruction in the fundamental branches can readily be integrated with the clinical experience. Particular emphasis should be placed on the study of pathology, and residents and fellows might well be required to examine both grossly and microscopically all urologic specimens removed during their term of service. Teaching rounds and departmental conferences are considered essential for systematic clinical instruction.

The department must provide adequate facilities for surgery and special urologic procedures.

Training in surgical technic should be sufficient to enable residents and fellows to undertake operative work on their own responsibility, especially toward the end of the graduate program.

The clinical material should be sufficient in amount and variety to fulfil the teaching needs of the service. It is generally assumed that a minimum of 200 inpatients a year is necessary for advanced training in urology. This amount should be supplemented by outpatient material in cystoscopic and general urologic clinics. Access to gonorrheal clinics would also be of advantage.

X. Resident-Intern Relationship

Those hospitals training both residents and interns should recognize their responsibility to both groups and not curtail too sharply the opportunities ordinarily given to interns by an excess of solicitude for the residents. The residents may, with profit, teach the interns, supervise their records and direct the treatments which interns administer. They should not, however, act so as to diminish the contact of the interns with the attending men or assume the supervisory or disciplinary functions of the staff intern committee.

XI. Recording of Credit

A successful completion of a residency or fellowship is recorded in the biographic files of the American Medical Association. It is important, therefore, that all institutions approved for fellowships and residencies in specialties make annual reports to this office. Periods of service in institutions approved by the Council for fellowships and residencies in

specialties are given full credit without further inquiry. Services in unapproved institutions are recorded as unclassified assignments.

Arrangements are now being made for an interchange of information between the Council and the examining boards responsible for the certification of specialists. In this way the study and appraisal of residencies and fellowships will lead to the formulation of lists approved by the Council and acceptable to the respective boards.

The specialty boards listed below have been approved by the Council in accordance with the following resolutions of the House of Delegates:

Resolved, That the Council on Medical Education and Hospitals is hereby authorized to express its approval of such special examining boards as conform to the standards of administration formulated by the Council; and be it further

Resolved, That the Board of Trustees of the American Medical Association be urged to use the machinery of the American Medical Association, including the publication of its Directory, in furthering the work of such examining boards as may be accredited by the Council.

American Board of Anesthesiology, Inc.,
Paul M. Wood, M.D., Secretary-Treasurer,
745 Fifth Avenue, New York.

American Board of Dermatology and Syphilology,
C. Guy Lane, M.D., Secretary-Treasurer,
416 Marlboro Street, Boston.

American Board of Internal Medicine, Inc.,
William S. Middleton, M.D., Secretary-Treasurer,
1301 University Avenue, Madison, Wis.

American Board of Obstetrics and Gynecology,
Paul Titus, M.D., Secretary-Treasurer,
121 South Highland Avenue, Pittsburgh.

American Board of Ophthalmology,
John Green, M.D., Secretary-Treasurer,
6830 Waterman Avenue, St. Louis

American Board of Orthopaedic Surgery, Inc.,
Fremont A. Chandler, M.D., Secretary-Treasurer,
6 North Michigan Avenue, Chicago.

American Board of Otolaryngology,
William P. Wherry, M.D., Secretary-Treasurer,
107 South Seventeenth Street, Omaha.

American Board of Pathology, Inc.,
Frank W. Hartman, M.D., Secretary-Treasurer,
2799 West Grand Boulevard, Detroit.

American Board of Pediatrics, Inc.,
C. Anderson Aldrich, M.D., Secretary-Treasurer,
723 Elm Street, Winnetka, Ill.

American Board of Psychiatry and Neurology, Inc.,
Walter Freeman, M.D., Secretary-Treasurer,
1028 Connecticut Avenue N.W., Washington, D. C.

American Board of Radiology, Inc.,
Byrl R. Kirklin, M.D., Secretary-Treasurer,
102 Second Avenue S.W., Rochester, Minn.

American Board of Surgery, Inc.,
J. Stewart Rodman, M.D., Secretary-Treasurer,
225 South Fifteenth Street, Philadelphia.

American Board of Urology, Inc.,
Gilbert J. Thomas, M.D., Secretary,
1009 Nicollet Avenue, Minneapolis.

XII. Admission to the Approved List

Institutions that wish to be approved for residencies or fellowships should apply to the Council on Medical Education and Hospitals of the American Medical Association, 535 North Dearborn Street, Chicago. Application blanks will be furnished and arrangements made for a personal visit of inspection by a member of the Council's staff. Approval is based on full compliance with the foregoing standards. Recognition may be withdrawn whenever it appears that the institution no longer conforms to these Essentials or when the positions remain vacant for a period of two or more years.

ESSENTIALS FOR APPROVED EXAMINING BOARDS IN SPECIALTIES

Revised May 15, 1939

I. Organization

1. A special examining board to be approved by the Council should represent a well recognized and distinct specialty of medicine.
2. It should be composed of representatives of the national organizations of that specialty including the related section of the American Medical Association.
3. It should be incorporated.
4. A special board should:
 - a. Determine whether candidates have received adequate preparation as defined by the board.
 - b. Provide a comprehensive test of the ability and fitness of such candidates.
 - c. Certify to the competence of those physicians who have satisfied the requirements of the board.

II. Definition of Special Fields

The following branches of medicine at present are recognized as suitable fields for the certification of specialists:

- | | |
|------------------------------|--------------------------------|
| 1. Internal Medicine | 7. Dermatology and Syphilology |
| 2. Surgery | 8. Neurology and Psychiatry |
| 3. Pediatrics | 9. Urology |
| 4. Obstetrics and Gynecology | 10. Orthopedic Surgery |
| 5. Ophthalmology | 11. Radiology |
| 6. Otolaryngology | 12. Pathology |
| | 13. Anesthesiology |

III. Qualification of Candidates

Each applicant for admission to the examination should be required to present evidence that he has met the following standards:

A. General Qualifications.

1. Satisfactory moral and ethical standing in the profession.
2. A license to practice medicine.
3. Membership in the American Medical Association is recommended.

B. Professional Education.*

1. Graduation from a medical school of the United States or Canada recognized by the Council on Medical Education and Hospitals of the American Medical Association.
2. Completion of an internship of not less than one year in a hospital approved by the same Council.

C. Special Training.**

(To be effective not later than Jan. 1, 1942.)

1. A period of study after the internship of not less than three years in clinics, dispensaries, hospitals or laboratories recognized by the same Council as competent to provide a satisfactory training in the special field of study.
2. This period of specialized preparation shall include,
 - a. intensive graduate training in anatomy, physiology, pathology, and the other basic medical sciences which are necessary to the proper understanding of the disorders and treatment involved in the specialty in question;
 - b. an active experience of not less than eighteen months in hospitals, clinics, dispensaries or diagnostic laboratories recognized by the Council as competent in the specialty;
 - c. examinations in the basic medical sciences of a specialty as well as in the clinical, laboratory and public health aspects.
3. An additional period of not less than two years of study and/or practice.

IV. Withdrawal

For reasons which are deemed sufficient, in the judgment of the Council on Medical Education and Hospitals, the recognition extended by the American Medical Association to holders of certificates from special examining boards may be withdrawn.

* Candidates who submit credentials from institutions outside of the United States and Canada should be required to pass the examination of the National Board of Medical Examiners.

** Candidates whose special training has been received outside of the United States and Canada should submit credentials satisfactory to the examining boards.

APPROVED EXAMINING BOARDS IN MEDICAL SPECIALTIES

The announcements of approved examining boards in medical specialties are reproduced herewith.

AMERICAN BOARD OF ANESTHESIOLOGY, Inc. AN AFFILIATE OF THE AMERICAN BOARD OF SURGERY

T. DRYSDALE BUCHANAN, President, New York.
HENRY S. RUTH, Vice President (Liaison Officer to the American Board of Surgery), Merion, Pa.
PAUL M. WOOD, Secretary-Treasurer, 745 Fifth Avenue, New York.
JOHN S. LUNDY, Rochester, Minn.
E. A. ROVENSTINE, New York.
H. BOYD STEWART, Tulsa, Okla.
RALPH M. TOVELL, Hartford, Conn.
RALPH M. WATERS, Madison, Wis.
PHILIP D. WOODBRIDGE, Boston.

HISTORY

The plan for this organization was devised to conform with those of other examining boards in medical specialties, by a committee representing the American Society of Anesthetists, Inc., the American Society of Regional Anesthesia, Inc., and the Section on Surgery of the American Medical Association. These organizations adopted the tentative plans submitted, and the formation of the American Board of Anesthesiology, Inc., an affiliate of the American Board of Surgery, Inc., was completed on June 2, 1937. The Advisory Board for Medical Specialties, and the Council on Medical Education and Hospitals of the American Medical Association approved the affiliation in 1938. Diplomates of this Board will be designated "A.B. 13" in the Directory and Biographical Departments of the American Medical Association.

PERSONNEL

The members of the examining board were elected by the American Society of Regional Anesthesia, Inc., the American Society of Anesthetists, Inc., and the Section on Surgery of the American Medical Association. Each cooperating society has three representatives, thus giving national and regional representation in the composition of the board.

The term of membership is for six years. Each cooperating association has the appointing power of its representatives subject to the approval of the board.

PURPOSES

1. To establish criteria of fitness to be designated a specialist in the practice of anesthesiology.
2. To improve educational facilities and practice in medical schools and hospitals, and furnish lists of these, together with lists of individual instructors who give adequate instruction and training in anesthesiology.

3. To arrange, control, and conduct examinations to determine the qualifications, and grant a certificate to those who voluntarily apply and meet the required standards. Such certification will serve to provide the public and the professions with the opportunity to select the best available service.

(Conferring of degrees is a prerogative of the universities, and the Board of Anesthesiology makes no attempt to grant degrees, regulate or control the practice of anesthesiology in any way whatsoever, by license or restriction.)

QUALIFICATIONS FOR ELIGIBILITY TO CERTIFICATION

A. *General*.—1. An applicant's moral and ethical standing in the profession must be satisfactory to the entire board. The board must be assured that the applicant is engaged in the practice of anesthesiology as a specialty and that he intends to continue to be so engaged.

2. Membership is required in the American Medical Association or membership in such other medical societies as are recognized for this purpose by the Council on Medical Education and Hospitals of the American Medical Association. Membership in other societies shall not be required.

3. Practice must be limited to anesthesiology, in accordance with the requirements of the American Board of Surgery.

4. In exceptional instances the board may, in its discretion, accept for examination candidates who have met all the preliminary requirements and have clearly demonstrated their identity as an anesthetist over a period of years but whose formal training does not comply with the full requirements to be exacted in the future.

B. *Professional Standing*.—1. An applicant must be a graduate of a grade A school in the United States or Canada recog-

nized by the Council on Medical Education and Hospitals of the American Medical Association, or a graduate of an approved foreign school.

2. Satisfactory evidence must be supplied of completion of an internship of not less than one year in a hospital approved by the same council, or its equivalent in the opinion of the board.

3. An applicant must establish in a manner satisfactory to the Board of Anesthesiology: that he is a physician duly licensed by law to practice medicine; that he is of high ethical and professional standing, and that he has received adequate special training in anesthesiology.

C. *Special Training and Practice*.—1. Before certification the candidate must have had an active experience limited to anesthesiology of not less than four calendar years.

2. The board recommends the inclusion of at least two years of carefully supervised instruction in the clinical phases of anesthesiology in hospital clinics, dispensaries, and diagnostic laboratories recognized by the Council on Medical Education and Hospitals of the American Medical Association as competent in the teaching and practice of anesthesiology. In addition, instruction in anatomy, physiology, pharmacology, biochemistry and other basic sciences which are necessary to the proper understanding of the problems involved in the specialty of anesthesiology is required.

(The board believes that for those entering the specialty after Jan. 1, 1942, the facilities for special training in anesthesiology will be increased and such training will be sufficiently standardized that special training in anesthesiology may be interpreted to include after that date:

- (a) A period of study, after the internship, of not less than three years in clinics, dispensaries, hospitals, and laboratories recognized by the Council on Medical Education and Hospitals of the American Medical Association as competent to provide a satisfactory training in the special field of anesthesiology.

- (b) A total period of not less than six years of special training and practice in anesthesiology after internship will be required before certification can be granted.)

EXAMINATIONS

The qualifying examination will be divided into Part I, written, Part II, oral, and Part III, practical.

PART I

1. An applicant, to be eligible for Part I, must meet all requirements and be certified by the central office of the board after his credentials have been approved by the secretary of the board, who shall have recourse to the Examination Committee in doubtful cases.

2. At the board's discretion a candidate may apply for the written examination on basic science and clinical practice on the completion of his courses of special training in these subjects.

3. Part I may be given simultaneously in several centers, throughout the United States, which the board may determine suitable for the purpose.

PART II

1. In order to be eligible for Part II, a candidate must have successfully passed Part I in addition to having met the necessary requirements and having presented definite evidence of an adequate experience in anesthesiology satisfactory to the board.

2. It is probable that Part II examinations will be held at the same time and place as the examinations of the American Board of Surgery. Later, however, as the demand grows, it may be necessary to establish subsidiary centers where this part may be held. At that time it will be necessary for the board to appoint subsidiary boards, consisting of those already qualified to actually conduct such examinations.

PART III

1. It is believed that the practical examination in this field is slightly different from that in most specialties. The examiners would be expected to observe the work of candidates in their own or similar operating room surroundings, their relations to other staff members, and investigate their professional standing.

CONDUCT OF EXAMINATION

Carefully conducted and thorough examinations will be required of candidates. The aim will be to avoid unduly exacting standards above present facilities for study and practice in anesthesiology, and on the other hand, to prevent laxity.

MEDICAL EDUCATION

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY

HOWARD FOX, President, New York.
HAROLD N. COLE, Vice President, Cleveland.
C. GUY LANE, Secretary-Treasurer, 416 Marlboro Street, Boston.
CHARLES C. DENNIE, Kansas City, Mo.
J. GARDNER HOPKINS, New York.
PAUL A. O'LEARY, Rochester, Minn.
ARTHUR W. STILLIANS, Chicago.
FRED D. WEIDMAN, Philadelphia.

ORGANIZATION

At the 1931 meeting of the American Dermatological Association, a committee was appointed to determine the advisability of forming an American Board for the certification of competent practitioners in our specialty similar to boards created by the ophthalmologists, the otolaryngologists and by the obstetricians and gynecologists. A similar committee was appointed by the Section on Dermatology and Syphilology of the American Medical Association at its meeting in the same year. A favorable report was rendered by each committee at the 1932 meeting of each of the above organizations.

The American Dermatological Association voted to accept the report of this committee, and the president appointed the following four members to represent the Association on the newly formed American Board of Dermatology and Syphilology:

Dr. Jay F. Schamberg, Philadelphia.
Dr. Harold Fox, New York.
Dr. Arthur W. Cole, Cleveland.
Dr. Arthur W. Stillians, Chicago.

The Section on Dermatology and Syphilology of the American Medical Association also accepted the report of its committee and the chairman appointed the following members to serve as its representatives:

Dr. Howard Morrow, San Francisco.
Dr. William H. Mook, St. Louis.
Dr. George M. MacKee, New York.
Dr. C. Guy Lane, Boston.

The first meeting of the board was held in New Orleans on May 11, 1932, at which time officers were elected. The president and secretary were then appointed a committee to prepare rough drafts of by-laws, certificate of incorporation, booklet of information, etc., to be submitted to the entire board.

Another meeting was held on Nov. 11, 1932, in Philadelphia at which the organization was completed and resolutions were adopted concerning the proper procedure to be followed by the board. On Nov. 29, 1932, the board was incorporated under the laws of the state of Delaware.

PURPOSES

The board has been established primarily to determine the competence of physicians who specialize in dermatology and syphilology. It will prescribe adequate standards of fitness, conduct examinations to test the qualifications of voluntary candidates and grant certificates to candidates who successfully fulfil the requirements of the board.

A second object is to publish lists of physicians, who shall have been certified by the board, for the benefit of hospitals, medical schools, other physicians and the lay public.

A third object is to improve the standards of practice of dermatology and syphilology (1) by investigation and encouragement of adequate facilities for graduate instruction in this specialty.

CERTIFICATES

A certificate will be issued to each candidate who meets the requirements of the board, to the effect that the holder of the certificate has had adequate training in dermatology and syphilology and has successfully fulfilled the requirements of the board.

It is expected that medical schools, hospitals and physicians, as well as the lay public, will utilize the certificate from this board as a proof of adequate preparation in the field of dermatology and syphilology, and of fitness of candidates for positions under their control. For this purpose lists of those holding certificates from the board will be available for inspection and will be published from time to time by the board. Diplomates will be identified in the Directory of the American Medical Association.

A certificate granted by this board does not of itself confer or purport to confer, any degree, or legal qualifications, privi-

which would nullify the main purpose of the certificate. Thus the type of the examination will depend on a careful review of the work done, years of practice, special courses of study, and professional standing of the applicant.

Written examinations will cover such topics as anatomy, biochemistry, physiology, pharmacology, pathology, physical diagnosis, therapeutics, clinical practice, and public health in relation to anesthesiology.

Oral examinations will cover topics in the above list, and such questions on physics and mechanics as are important in anesthesiology, especially dealing with electrical theories and the proper handling of high pressure gases and flammable agents.

Practical demonstrations will be required of the use of various types of apparatus and techniques. Cadavers may be utilized by the candidates to demonstrate anatomical landmarks and techniques important in regional anesthesia and for therapeutic and diagnostic procedures. Candidates should also be prepared to demonstrate methods of artificial respiration, and intravenous and pneumothorax.

GRADES

A candidate must receive a passing average for each part, to be entitled to certification. No candidate shall pass a part who does not receive a grade of 60 per cent or more in each subject of such part. An average grade of 75 per cent shall be required for passing.

A candidate who fails in his examination in Part I will have his papers reviewed by the entire board and will be entitled to reexamination at yearly intervals for two consecutive years without further payment of fee. The board may, however, for sufficient reason, deny a candidate the privilege of reexamination.

FEES

The fee shall be \$50, \$25 of which shall be paid on filing the application. The remaining \$25 shall be paid before taking the examinations. A filing fee of \$5 must accompany each application. This fee will not be returned in case of rejection but will be applied to the total fee if the application is accepted.

This board is a nonprofit organization, all fees to be used to extend the existing facilities for training in anesthesiology, after deducting necessary expenses for maintenance of the office, and the conducting of examinations. The board reserves the right to increase the fee when found necessary.

REVOCATION OF CERTIFICATE

All certificates issued by the board shall be subject to revocation by the board at any time, in case it shall determine in its sole judgment that a candidate who has received a certificate either was not properly qualified to receive it or has become disqualified since its receipt.

ADDITIONAL INFORMATION

Every candidate applying for certification must personally appear before the board before being certified. Application blanks may be secured through the Secretary of the American Board of Anesthesiology. They must be completely filled out, accompanied by the other required credentials, and filed with the secretary of the board at least sixty days prior to the date of examination. Application blanks contain the following statement:

"I hereby make application to the American Board of Anesthesiology, Inc., an affiliate of the American Board of Anesthesiology, Inc., for the issuance to me of a Certificate of Qualification as a Specialist in Anesthesiology and for examination relative to a Certificate of Qualification from examination or from the issuance of such Certificate of Qualification in the event that any of the regulations, and enclose fee of Fifty Dollars (\$50.00). I agree to disqualification from examination or from the issuance of such Certificate of Qualification in the event that any of the rules governing such examinations are violated by me or hereinafter made by me are false or in the event that any of the provisions of the Certificate of Incorporation or By-Laws of the American Board of Anesthesiology, Inc., an affiliate of the American Board of Anesthesiology, Inc., its members, examiners, officers and agents free from any damage or complaint by reason of this application, such examinations, the grade or grades given with respect to any examination, or the failure of said Board or Corporation to issue to me such Certificate of Qualification."

Proper forms for making application and other information will be furnished by the secretary.

* This may be paid as follows: \$25 with application, and \$25 before examination.

leges, or license to practice dermatology or syphilology. The board does not intend to limit or interfere with the professional activity of any duly licensed physician. Its aim is to elevate the standard of qualification for specialists in our field and to certify as specialists those who voluntarily comply with the requirements of the board.

Certificates will be issued only to physicians in the United States and its possessions, in Canada and in Cuba.

APPLICATION AND FEE

The board desires to appraise the candidate's educational opportunities (premedical, medical and dermatologic), the character of the men under whom he has worked, his hospital and teaching positions, original investigations, contributions to dermatologic literature, membership in medical societies and his local and general reputation.

For this purpose, application must be made on a special blank, which may be obtained from the secretary. No application will be considered unless made on the regular application blank. This application should be forwarded at least two months before the date of examination together with the required reprints, photographs and the fee of \$35. This fee will not be returned, and no application will be considered until the fee is received. This fee has been carefully computed and is used entirely for administrative purposes. Members of the board do not receive any compensation except for actual expenses connected with holding the examinations.

Make checks payable to American Board of Dermatology and Syphilology, Inc.

EXAMINATIONS

Applicants classified in group B will be required to pass a written examination. This written examination on clinical and laboratory subjects including cutaneous pathology will be held simultaneously at stated intervals in different parts of the country, approximately two months before the oral examination.

Applicants classified in both groups A and B will be required to pass an oral, clinical and laboratory examination. This examination will be conducted in a clinic or hospital ward where individual cases will be discussed with each candidate. The examination will include the following subjects as related to the skin: histopathology, mycology, allergy, and physics of physical therapy.

The oral examination will be held near the time and place of the annual meeting of the American Academy of Dermatology and Syphilology. This examination will be held only at the time of regular meetings of the board.

Examinations are designed to test the candidate's fitness to practice dermatology and syphilology as a specialty. The board will endeavor to adapt this examination to the candidate's experience and years of practice. It will try especially to ascertain the breadth of his clinical experience, his knowledge of recent literature of dermatology and syphilology and his general qualifications as a specialist in this branch of medicine.

Except in special circumstances, applicants shall take the examination within the year following the filing of application and the deposit of the fee.

Whenever an applicant fails to pass the examination, the board if requested will make suggestions as to suitable courses of instruction for the purpose of overcoming deficiencies in his knowledge of the specialty.

Beginning in 1940 the examination will include the following additional subjects as related to the skin: parasitology, serology and embryology.

REEXAMINATIONS

If the candidate fails or is "conditioned" in an examination he will be admitted to a second examination after one year, but within three years, and must give sixty days' notice of his intention to appear for reexamination. If a candidate who has failed or has been conditioned does not appear for reexamination before the expiration of three years, he will be required to make a new application and pay an additional fee of \$35 before reexamination.

A candidate having failed twice must file a new application and pay an additional fee of \$35.

REQUIREMENTS FOR CERTIFICATION

I. GENERAL REQUIREMENTS

1. High ethical and professional standing.
2. Graduation from a medical school of the United States or Canada recognized by the Council on Medical Education and Hospitals of the American Medical Association.
3. A license to practice medicine.
4. Satisfactory completion of an internship of not less than one year in a hospital approved by the same Council.

5. Membership in the American Medical Association or, by courtesy, membership in such Canadian or other medical societies as are recognized for this purpose by the Council on Medical Education and Hospitals of the American Medical Association. Except as here provided, membership in other societies is not required.

6. Adequate training in dermatology and syphilology as a specialty. Each applicant must be known personally to one member of the board.

II. SPECIAL REQUIREMENTS

Applicants for certification by the board are classed in two groups as follows:

Group A consists of physicians who have limited their practice mainly to dermatology and syphilology for ten or more years, including a period of training satisfactory to the board.

Group B consists of physicians who have practiced dermatology and syphilology at least five years, including their period of training. Such applicants must have had at least two full years of special training devoted exclusively to dermatology and syphilology, including at least one year in a well recognized clinic or as an assistant in the private practice of a well known specialist in this field.

III. FUTURE SPECIAL REQUIREMENTS

For group B candidates to be examined from Jan. 1, 1940, to Jan. 1, 1945, the board will require two years of full-time planned training in clinical dermatology and syphilology, including adequate instruction in the following subjects related to the skin: histopathology, mycology, physics as related to physical therapy, and allergy.

Beginning Jan. 1, 1945, additional requirements will become effective. By 1940 it is expected that sufficient facilities will be developed throughout the country to provide for three years' training of graduate students in accordance with the minimum requirements suggested by the Advisory Board for Medical Specialties and outlined in a Syllabus issued by the board. These minimum requirements of special training for admission to examination in 1945 shall be as follows:

1. A period of study after the internship of not less than three years in clinics, dispensaries, hospitals or laboratories recognized by the same Council and approved by the American Board of Dermatology and Syphilology as competent to provide a satisfactory training in dermatology and syphilology.

2. This period of specialized training shall include:

(a) Graduate training in the basic medical sciences which are necessary to the proper understanding of the disorders and treatment involved in this specialty.

The following fundamental subjects as related to the skin are deemed necessary by the board: embryology, histology, chemistry, physiology, bacteriology, mycology, parasitology, pathology, immunology, serology, pharmacology and materia medica, and physics of physical therapy.

(b) An active experience of not less than eighteen months in hospitals, clinics, dispensaries or diagnostic laboratories recognized by the same Council and approved by the American Board of Dermatology and Syphilology as competent to provide an adequate preparation.

(c) Examinations in the basic medical sciences of a specialty as well as in the clinical, laboratory and public health aspects.

3. An additional period of not less than two years of study and/or practice.

Therefore, candidates beginning their training after Jan. 1, 1940, for certification by this board must plan for a three years course of systematic training as stated in the Syllabus.

In 1945 and thereafter admission to examination by this board will be permissible only to applicants with such training. Classes A and B will be abolished and all candidates will be required to fulfil the same requirements.

REVOCATION OF CERTIFICATES

The certificates issued by the board are issued subject to the provisions of the certificate of incorporation and of the by-laws, and each certificate is subject to revocation in the event that:

(a) the issuance of such certificate or its receipt by the physician so certified shall have been contrary to any of the provisions of the certificate of incorporation or by-laws; or

(b) the physician so certified shall not have been eligible to receive such certificate, irrespective of whether or not the facts constituting him so ineligible were known to or could have been ascertained by the directors of the Board at the time of the issuance of such certificate; or

(c) the physician so certified shall have made any misstatement of fact in his application for such certificate or in any other statement or representation to the Board or its representatives; or

(d) the physician so certified shall have been convicted by a court of competent jurisdiction of a felony or of any misdemeanor involving, in the opinion of the Board of Directors, moral turpitude in connection with his practice of medicine; or

(c) the physician so certified shall have had his license to practice medicine revoked or shall have been disciplined or censured as a physician by any court or other body having proper jurisdiction and authority.

INSTRUCTIONS TO APPLICANTS

Fill out application blank in detail.
Enclose fee of \$35. (Make checks payable to the American Board of Dermatology and Syphilology, Inc.)
Include photograph as directed on application blank.
Enclose reprint of each published paper, if possible.
Send completed applications and above items to the secretary.
Please indicate under No. 13 on the application blank as complete data as possible about your training in dermatology and syphilis. Indicate the month and year, if possible, or at least the number of months of the various parts of your training and also whether full time or part time. If part time indicate whether one-half day, six days a week or three days a week, etc. dispensary service is considered as part of your trainings.
In No. 16 indicate clearly when you limited your practice to dermatology and syphilis.
If your training and your practice overlap, please explain under No. 19.

PUBLICATIONS OF THE BOARD

1. Booklet of Information.
2. Opportunities for Graduate and Postgraduate Students in Dermatology and Syphilology, containing a list of places where instruction may be obtained, and details about these places.
3. Registry of Diplomates, containing alphabetical and geographical lists of diplomates of the board.
4. Syllabus, in preparation,
 - (a) To inform the student physician, intending to specialize, of the field to be covered in his preparation and the methods by which it can be accomplished.
 - (b) To aid the medical schools and the dermatological departments of teaching required for specialization in dermatology and syphilology.

AMERICAN BOARD OF INTERNAL MEDICINE, Inc.

ERNEST E. IRONS, Chairman, Chicago.
REGINALD FITZ, Vice Chairman, Boston.
WILLIAM S. MIDDLETON, Secretary-Treasurer, 1301 University Avenue, Madison, Wis.
DAVID P. BARR, St. Louis.
LOUIS HAMMAN, Baltimore.
WILLIAM J. KERR, San Francisco.
JONATHAN C. MEAKINS, Montreal, Canada.
JOHN H. MUSSER, New Orleans.
G. GILL RICHARDS, Salt Lake City.

"... the membership of the Board shall be maintained at the ratio of five members from the American College of Physicians and four members from the Section on the Practice of Medicine of the American Medical Association and that at least three of the members of the Board from the American College of Physicians and two members of the Board from the Section on the Practice of Medicine of the American Medical Association shall be of professorial rank in approved medical schools of the United States or Canada."

"Sec. 5, Art. 5, Articles of Incorporation."
"The term of office of members of the Board succeeding the original Board members shall be three years and until their successors are elected and qualified, and no such member shall serve more than two consecutive three year terms."

"Sec. 7, Art. 5, Articles of Incorporation."

HISTORY AND AUTHORITY FOR ORGANIZATION

The American College of Physicians, through its Board of Regents at the annual session in Philadelphia, on April 30, 1935, adopted a resolution for the establishment, with the Section on the Practice of Medicine of the American Medical Association, of an "American Board for the Certification of Internists." This board to consist of nine members; six to be appointed by the American College of Physicians, and three by the Section on the Practice of Medicine of the American Medical Association. The expenses attending the organization were to be underwritten by the American College of Physicians.

It was further resolved that the American College of Physicians make representations to the Association of American Physicians, acquainting them with the plan of the American College of Physicians for the establishment of a national examining board for the certification of internists, and asking for their comments and cooperation.

This association, through its secretary, advised the American College of Physicians that the above resolution was considered by the Council of the Association at a meeting on May 8, 1935, and that the Council could take no action in the matter as the problem was outside the scope of the activity of that association.

At the annual meeting of the American Medical Association at Atlantic City, N. J., June 10-14, 1935, the Section on the Practice of Medicine adopted the following resolution: "Resolved, that a committee of three, including a chairman be appointed by the chairman of the Section on the Practice of Medicine, to discuss with a committee from the American College of Physicians ways and means whereby an examining board, comparable to such boards already existing in certain specialties, may be set up for the purpose of certification of specialists in internal medicine."

President James Alexander Miller of the American College of Physicians appointed the following as representatives of the college on the joint committee, Jonathan C. Meakins, Montreal; O. H. Perry Pepper, Philadelphia; David P. Barr, St. Louis; John H. Musser, New Orleans; William S. Middleton, Madison, and G. Gill Richards, Salt Lake City.

Chairman William J. Kerr appointed as representatives from the Section on the Practice of Medicine of the American Medical Association Ernest E. Irons, Chicago; Reginald Fitz, Boston, and Walter L. Bierring, Des Moines.

The latter was named as chairman of the joint committee. The joint committee of nine members held its first meeting in Philadelphia, Dec. 14, 1935, at the office of the American College of Physicians. At this meeting a resolution was adopted to submit an application in due form to the Advisory Board for Medical Specialties, which board functions in conjunction with the Council on Medical Education and Hospitals of the American Medical Association, for authority to organize the American Board of Internal Medicine and for admission to membership in the Advisory Board for Medical Specialties. At the time of the consideration of the preliminary draft of the constitution and by-laws, the ratio of six and three from the board was changed. The ratio of six and three from the American College of Physicians and the Section on the Practice of Medicine of the American Medical Association, respectively, was changed to five from the American College of Physicians and four from the Section on the Practice of Medicine of the American Medical Association. This new ratio of representation was made a part of the constitution and remains as such. A committee was appointed consisting of Drs. Meakins, Fitz, Irons and Middleton to prepare the requirements for special training, which requirements were later incorporated in the by-laws.

On Feb. 16, 1936, a subcommittee of Drs. Bierring, Fitz, Irons, Meakins and Middleton, held a meeting in Chicago to formulate and complete the details of the application to be presented to the Executive Committee of the Advisory Board for Medical Specialists, which met in evening session, Feb. 16, 1936, and approved the organization of the American Board of Internal Medicine and directed that the articles of incorporation be completed and properly filed for record.

In keeping with the ratio of membership to be maintained on the American Board of Internal Medicine, James Alexander Miller, president, officially designated Jonathan C. Meakins, O. H. Perry Pepper, David P. Barr, William S. Middleton and G. Gill Richards as representatives from the American College of Physicians, and William J. Kerr, chairman, designated Reginald Fitz, Ernest E. Irons, John H. Musser and Walter L. Bierring to represent the Section on the Practice of Medicine of the American Medical Association.

The articles of incorporation were filed for record with the County Recorder of Polk County at Des Moines, Polk County, Iowa, Feb. 28, 1936.
At the annual session of the American College of Physicians, Detroit, Mich., March 1-6, 1936, the Board of Regents officially approved the American Board of Internal Medicine, and on May 10, 1936, the Advisory Board for Medical Specialties, meeting in Kansas City, gave its final approval to the American Board of Internal Medicine, granting at the same time admission to membership in the Advisory Board for Medical Specialties.

The Council on Medical Education and Hospitals of the American Medical Association approved the board, at its meeting May 12, 1936, and the Section on the Practice of Medicine gave its final approval May 13, 1936.

The first meeting of the board was held at the Palmer House, Chicago, June 14-15, 1936, at which time the officers were chosen for the ensuing year and action was taken as to methods of procedure, time, and place of holding the first written and practical examinations as well as the completion of the final details of administration.

PURPOSE AND OBJECTIVE

The purpose and objective of the board is the certification of specialists in the field of internal medicine, and the establishment of qualifications for such certification and of the procedure necessary for the accomplishment of such objective.

While the board is at present concerned chiefly with the qualification and procedure for certification in the general field of internal medicine, it is intended to inaugurate, as soon as practicable similar qualification and procedure for additional certification in certain of the more restricted and specialized branches of internal medicine, as gastro-enterology, cardiology, metabolic diseases, tuberculosis, allergic diseases, et cetera. Such special certification will be considered only for candidates who have passed the written examination required for certification in general internal medicine. The operation of such a plan will require the active cooperation and participation of recognized representatives from each of such special fields of medicine.

VALUE OF CERTIFICATION

1. An attest of special training and qualification for the practice of internal medicine as a specialty.

2. Publication with internists proper designation in a special registry of certified specialists and in the American Medical Directory.

QUALIFICATIONS OF CANDIDATES

Each applicant for admission to the examination shall be required to present evidence that he has met the following standards:

1. GENERAL.

A. Satisfactory moral and ethical standing in the profession.

B. Membership in the American Medical Association or, by courtesy, membership in such Canadian or other medical society or societies as are recognized for this purpose by the Council on Medical Education and Hospitals of the American Medical Association. Except as here provided, membership in other societies shall not be required.

2. PROFESSIONAL.

A. Graduation from a medical school of the United States or Canada approved by the Council on Medical Education and Hospitals of the American Medical Association.

B. Completion of an internship of not less than one year in a hospital approved by the same council.

C. In the case of an applicant whose training has been received outside of the United States and Canada, his credentials must be satisfactory to the aforementioned council, the Advisory Board for Medical Specialties, and the National Board of Medical Examiners.

3. SPECIAL TRAINING.

A minimum of five years must elapse after completion of a year of internship in a hospital approved for intern training before the candidate is eligible for admission to an examination.

A. Three years of this period must be devoted to special training in internal medicine. This requirement should indicate a period of at least several months of graduate work under proper supervision in anatomy, physiology, biochemistry, pathology, bacteriology or pharmacology, particularly as related to the practice of internal medicine. This work may be carried on in any domestic or foreign medical school or laboratory recognized by the Council on Medical Education and Hospitals of the American Medical Association as offering appropriate facilities for this type of postgraduate training; or it may include a period of at least several months of graduate work under proper supervision in internal medicine or in its restricted and specialized branches in any domestic or foreign hospital, clinic or dispensary, or under the immediate preceptorship of an internist recognized by the above council as offering appropriate facilities for this type of postgraduate experience.

B. A period of not less than two years of special practice in the field of internal medicine or in its more restricted and specialized branches.

MEMORANDUM FOR THE GUIDANCE OF CANDIDATES

The American Board of Internal Medicine does not propose to establish fixed rules for the preliminary training of candidates for certification in this field. Broad general principles for training, however, may be outlined, although such suggestions as are made must of necessity be subject to constant changes reflecting the dynamic nature of the specialty.

1. A sound knowledge of physiology, biochemistry, pharmacology, anatomy, bacteriology and pathology in so far as they apply to disease is essential for continued progress of the individual who practices internal medicine. Such knowledge may be obtained in a number of ways:

A. By properly arranged and supervised graduate courses;

B. By the opportunities for study afforded by the appointment to a junior position in a department of physiology, biochemistry, pathology, etc. (see above) with attendance upon advanced lectures in the other subjects;

C. By advanced study in these subjects while an intern or resident medical officer, and by the application of the principles involved to patients under one's control;

D. By the detailed study, under supervision, of a problem or topic in medicine in which the student brings the basic facts of physiology, pathology, etc., into direct relation with the concrete clinical problem. The analysis of a problem with detailed knowledge of its fundamental pathologic or physiologic background does much to stimulate thoroughness, clear thinking and progress.

2. A portion of the written examination is designed to test the candidate's knowledge in these "preclinical" subjects and especially in their application to disease rather than their purely laboratory aspects.

3. The mere factual knowledge of medicine and its basic sciences is not sufficient. The candidate must have had training in their use in furthering his understanding in clinical medicine. This implies practical experience under the guidance of older men who bring to their clinical problems ripe knowledge and critical judgment. Preparation to meet this requirement adequately may be even more difficult to obtain than the so-called scientific training. It may, however, be acquired in the following ways:

A. By work in a well organized hospital outdoor clinic conducted by competent physicians;

B. By a prolonged period of resident hospital appointments likewise directed by skilled physicians;

C. By a period of training in intimate association with a well trained and critical physician who takes the trouble to teach and guide his assistant rather than to expect him only to carry out the minor drudgery of a busy practice.

4. The board does not consider it to the best interests of internal medicine in this country that rigid rules be formulated as to where or how the training outlined above is to be obtained. Medical teaching and knowledge are international. The opportunities of all prospective candidates are not the same. Some may have the opportunity of widening their knowledge by a period of study abroad. Others, at the other extreme, may be restricted to a comparatively narrow geographic area and their more detailed training must be obtained in short periods of good study scattered over a longer time. Although it is required that at least five years must elapse between the termination of the first intern year and the date when the candidate is eligible to take the examination, a longer period is advisable. The board wishes to emphasize that time and training are but a means to the end of acquiring a broadness and depth of knowledge of internal medicine which the candidate must demonstrate to the board in order to justify it in certifying that he is competent to practice internal medicine as a specialty. The responsibility of acquiring the knowledge as best he may rests with the candidate, while the responsibility of maintaining the standard of knowledge required for certification devolves on the board.

METHOD OF EXAMINATION

The examination required of candidates for certification as specialists in internal medicine will comprise Part I (written), and Part II (practical or clinical).

Part I. The written examination is to be held simultaneously in different sections of the United States and Canada on the third Monday of February and October of each year. This examination will be divided into a morning and an afternoon session of three hours each, and the two sessions A and B will include the following:

A. Question in applied physiology, anatomy, physiological chemistry, pathology, bacteriology and pharmacology as related to internal medicine as well as the cultural aspects of medicine.

B. Questions in general internal medicine.
Part II. Candidates successful in the written tests will be eligible for the practical or clinical examination, which will be conducted by the members of the board* near the time and place of the annual meeting of the American College of Physicians and of the American Medical Association. This examination is conducted at the bedside, and each candidate will be assigned one or more patients in the hospital. A written record of the clinical history and examination is required which forms the basis of the oral conference conducted by one or more examiner.

APPLICATION

Candidates for examination shall make their application on a prescribed form which may be obtained from the office of the secretary-treasurer.

The application shall contain a record of the candidate's premedical and medical training as well as of internships, graduate study, hospital or dispensary staff appointments, teaching positions, membership in medical societies, medical papers published and the names of two well known internists to whom the board may refer for professional and character reference. The application shall also be accompanied by two recent, unmounted, signed photographs of the candidate and the registration and examination fee of \$40, which fee will cover both the written and practical examinations. The registration fee of \$10 is not refundable. An additional fee of \$10 will be required when the certificate is issued.

CERTIFICATES

The certificate issued by the American Board of Internal Medicine shall be in such form as to comply with the articles of incorporation and the by-laws and shall be signed by the officers and members of the board, and shall bear the official seal of the board. Certificates of the board will be issued to candidates who have satisfactorily completed the written and practical examinations, and been found qualified by the board to practice the specialty of internal medicine.

REVOCATION OF CERTIFICATES

The American Board of Internal Medicine shall have the sole power, jurisdiction and right to determine and decide whether or not the evidence or information placed before it is sufficient to constitute grounds for revocation of any certificate issued by this board, and the decision of the board in the premises shall be final. All official correspondence should be addressed to the secretary-treasurer.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY, Inc.

WALTER T. DANNREUTHER, President, New York.
JENNINGS C. LITZENBERG, Vice President, Minneapolis.
R. D. MUSSEY, Vice President, Rochester, Minn.
PAUL TITUS, Secretary-Treasurer, 121 South Highland Avenue, Pittsburgh.
E. A. SCHUMANN, Member of Executive Committee, Philadelphia.
JOSEPH L. BAER, Chicago.
G. D. ROYSTON, St. Louis.
LOUIS E. PHANEUF, Boston.
L. A. EMGE, San Francisco.

ORGANIZATION

In 1930 the American Association of Obstetricians, Gynecologists, and Abdominal Surgeons, the American Gynecological Society, and the Section on Obstetrics, Gynecology, and Abdominal Surgery of the American Medical Association, each elected three Fellows to constitute the American Board of Obstetrics and Gynecology. Dr. Walter T. Dannreuther of New York, Dr. Paul Titus of Pittsburgh and Dr. Grandison D. Royston of St. Louis were appointed to represent the American Association of Obstetricians, Gynecologists, and Abdominal Surgeons; Dr. Jennings C. Litzenberg of Minneapolis, Dr. Joseph L. Baer of Chicago, and Dr. E. A. Schumann of Philadelphia were appointed to represent the American Gynecological Society; Dr. Fred L.

* Additional examiners for the practical examination may be requested to be nominated by the Section on the Practice of Medicine of the American Medical Association and the Board of Regents of the American College of Physicians in the same ratio as their representation on the present board and from special societies when their services may be required.

Adair of Chicago, Dr. R. D. Mussey of Rochester, Minn., and Dr. E. D. Plass of Iowa City, Iowa, were appointed to represent the Section on Obstetrics and Gynecology of the American Medical Association. Dr. Adair and Dr. Plass were succeeded following their recent resignation by Dr. L. E. Phaneuf of Boston and Dr. L. A. Emge of San Francisco.

The board was incorporated and organized and held its first meeting in September 1930. At that time the By-Laws were adopted and provision was made by resolutions for its proper functioning.

This board had been in the process of organization since 1927 and puts into action a determined effort on the part of these three national organizations to improve the standards of practice of obstetrics and gynecology.

Experienced practitioners of the specialty are required to undergo a practical clinical examination, whereas a younger group has both a written and clinical examination and must also submit records of a group of cases in order to qualify for certification.

After 1941, no such distinction will be made, and all applicants will be obliged to fulfill all of the requirements, including the written examination and case records, as well as the general oral-clinical and pathological examination.

PURPOSES

First. To elevate the standards and advance the cause of obstetrics and gynecology.

Second. To determine the competence of specialists in obstetrics and gynecology.

Third. To grant and issue certificates, or other evidence of special knowledge in the field of obstetrics and gynecology, to voluntary applicants and candidates therefor.

Fourth. To arrange, control, and conduct examinations to test the qualifications of voluntary candidates.

Fifth. To serve the public, hospitals and the medical schools by preparing lists of practitioners who shall have been certified by the board. These activities proceed from the certificate of incorporation in which it is stated that "the nature of the business and the objects or purposes proposed to be transacted, promoted and carried on by it" are as follows: "To encourage the study, improve the practice, and advance the cause of obstetrics and gynecology, subjects which should be inseparably interwoven; and to grant and to issue to physicians duly licensed by law, certificates or other equivalent recognition of special knowledge in obstetrics and gynecology."

NO DEGREES OR LEGAL RESTRICTIONS

Each certificate granted or issued does not of itself confer or purport to confer upon any person any degree or legal qualifications, privileges or license to practice obstetrics or gynecology, nor does the board intend in any way to interfere with or limit the professional activities of any duly licensed physician. Its chief aim is to standardize qualification for specialists in obstetrics and gynecology, and to certify as specialists those who voluntarily comply with the board's requirements.

VALUE OF CERTIFICATE

The national obstetrical and gynecological organizations, which have participated in the formation of the board and are sponsoring its activities, as well as other societies, attach considerable importance to its certificate. Both the medical and the lay public, including hospital directors, have come to utilize the certificate from this board as a means of determining who are well grounded as specialists in obstetrics and gynecology.

Lists of those holding certificates from this board who are limiting their practice to obstetrics and gynecology are published and issued from time to time by the board; similar lists are published by the *American Journal of Obstetrics and Gynecology*, and also appear in the *American Medical Directory*. This latter indicates diplomates of this and other boards by means of numerical symbols appearing in the biographic records. This directory, however, does not give such special recognition to diplomates who fail to maintain membership in the American Medical Association, or the Canadian or other medical societies recognized for this purpose.

A joint directory of specialists certified by the fourteen existing special boards is to be published regularly beginning late in 1939.

This board holds active membership in the Advisory Board for Medical Specialties.

Applicants sign an agreement empowering the board to revoke their certificates and to remove their names from its lists, if they fail to abide by the regulations governing limitation of practice to the specialty or otherwise violate the standards of ethical practice.

For emphasis it is repeated that the board does not intend to, and cannot, in any way interfere with or limit the professional activities of any duly licensed physician, but its aim is toward adequate qualifications for those who claim to be specialists in obstetrics and gynecology.

ELIGIBILITY REQUIREMENTS

Requirements for Applicants. Each applicant, before he shall become eligible to receive such certificate or other evidence of recognition, (a) must establish in a manner satisfactory to the board of directors that he is a physician duly licensed by law to practice medicine, that he is of high ethical and professional standing, and that he has received adequate training in obstetrics and gynecology as a specialty; (b) must have had conferred upon him a degree in medicine by an institution of learning approved by the Advisory Board for Medical Specialties and the Council on Medical Education and Hospitals of the American Medical Association; (c) must make application to the examiners whose duty it shall be to investigate the applicant's credentials and make a survey of his character; (d) must assure the board that he is limiting his practice to obstetrics and/or gynecology and that he intends to continue to do so, and (e) must have membership in the American Medical Association, or membership in such Canadian or other medical societies as are recognized for this purpose by the Council on Medical Education and Hospitals of the American Medical Association. Membership in other societies is not required.

Each candidate should have certain fundamental knowledge of the basic essentials of anatomy, pathology, bacteriology, physiology, pharmacology, and therapeutics as related to the practice of obstetrics and gynecology. Clinical training should consist, subsequent to graduation, of at least one year's general rotating internship, and thereafter a special residency in obstetrics and gynecology for a period of at least three years not necessarily consecutive. The board accepts the fifth or "intern" medical school year required at some schools in lieu of the usual fifth or intern "clinical training" year following graduation. As a substitute for such training, service with a qualified preceptor, preferably one who has been certified by the board, may be acceptable. The exact time basis for this has not been specified, and each case will be reviewed and decided separately by the credentials committee. The time for this type of training will vary with the amount of work done with the preceptor. At least a fundamental knowledge of both obstetrics and gynecology is essential regardless of whether a candidate's practice is limited to one or the other branch.

This board deprecates the practice of obstetricians and gynecologists engaging in other fields of practice than that in which they profess to be specialists. The board does not exclude from examination, however, obstetricians or gynecologists who practice abdominal surgery and urology in the female, as well as breast surgery, because of the correlation of these activities. The board has ruled that physicians who accept male patients in their private or other practice, for operative or other care, cannot be regarded as specialists in obstetrics and gynecology. Special certifying boards in general surgery and internal medicine have now been organized and such individuals should apply to these boards for certification.

Application must be on a special blank which may be procured from the secretary and forwarded with the other required credentials and the application fee. Applications must be in the office of the secretary at least sixty days prior to the date of examination.

CLASSIFICATION OF APPLICANTS

Until Jan. 1, 1942, applicants for such certificates or other recognition shall be classified by the credentials committee as follows:

Group A. Those who have limited their practice to obstetrics and/or gynecology for a period of ten years or more, having had adequate special training following a one year general internship.

Applicants who shall have qualified under group A shall be required to undergo and pass a practical, oral, clinical and laboratory examination, including obstetrical and gynecological pathology. The board of directors may grant and issue a certificate, or other evidence of recognition to each such applicant who shall have passed such examination in a manner and with a grade satisfactory to the board of directors, and who shall have met all other requirements thereof as hereinabove provided. (After 1941 case records and written examinations will also be required as at present for group B.)

Group B. Those who have had: (1) at least one year of intern service in a hospital approved by the Council on Medical Education and Hospitals of the American Medical Association,

(2) five years or more practice thereafter, including at least three years of special training in obstetrics and/or gynecology satisfactory to the board of directors, and (3) who are now limiting their practice to obstetrics and/or gynecology. Opportunity for personal responsibility during this period of training is highly desirable.

Applicants who have qualified under group B shall be required to take and pass a written clinical and laboratory examination in obstetrics and gynecology, including obstetrical and gynecological pathology, as well as an oral, practical examination. Each candidate shall submit 50 typewritten case reports of major pathological obstetrical and/or gynecological cases with or without operative procedures. Candidates must attain a passing grade in both the written examination and case histories before becoming eligible for the oral, clinical, and pathological part of the examination. The board of directors may grant and issue a certificate to each such candidate who shall have passed such examination and who shall have submitted reports on such cases in a manner and with a grade satisfactory to the board of directors, and who shall have met all other requirements as hereinabove specified.

Effective Jan. 1, 1942, the requirements for all candidates will be changed to be as follows: Those who have had: (1) at least one year of intern service in a hospital approved by the Council on Medical Education and Hospitals of the A. M. A., (2) a minimum of seven years of practice thereafter, including at least three years of special training in obstetrics and/or gynecology satisfactory to the board of directors, and (3) who are now limiting their practice to obstetrics and gynecology. Opportunity for personal responsibility during their period of training is highly desirable.

APPLICATION BLANK AND FEES

Application must be made on a special blank which may be procured from the secretary and forwarded with the other required credentials and the application fee. The secretary cannot make any eligibility rulings. These are made only by the credentials committee after reviewing the candidate's formal application, which must be completely filled out and previously filed with the secretary. Applications cannot be considered for classification and action by the credentials committee unless accompanied by an application fee of \$10, which is not returnable.

The examination fee for candidates is \$85, payable when the candidate is notified of his acceptance for examination. This examination fee shall not be returnable after the candidate has been officially accepted by the credentials committee and notified to report for examination. If a candidate fails in his examination he will be admitted to a second examination after one year but within three years without additional fees. After two failures an applicant must file a new application and pay fees, as above, before the third examination.

Applicants declared ineligible for admission to examination may reopen their applications within one year of its filing date without payment of an additional application fee.

Applications and application fees must be in the office of the secretary at least ninety days prior to the scheduled date of the examinations.

The fees, totaling \$100, have been carefully computed on a basis of cost of examinations and are used entirely for administrative expenses. Examiners serve without compensation other than actual expenses.

Applicants who fail to exercise the examination privilege within three years of the date of filing the application are required to file a new application and pay a new application fee.

EXAMINATIONS

Written examinations are held simultaneously once yearly in various cities of this country and Canada. Arrangements will be made for candidates to report in any convenient city where there may be a diplomate of this board to conduct or supervise the written examination sent out under sealed cover from the board's office. Case histories must be submitted to the local examiner at the same time.

The written examination and submission of case histories are scheduled for the first Saturday of January. Application on an official application form for admission to these examinations must be filed in the office of the secretary at least ninety days prior to these dates.

Part I of the examination must be taken by all applicants classified in group B, but not by those in group A until 1942.

Part I consists of a comprehensive written examination and the filing of fifty case histories. Only one group B, Part I, examination will be held yearly. No group B candidate is eligible for the oral and pathological examinations until he has passed the written portion and his case histories have been

found satisfactory. The passing grade for the written examination and case records is 75 per cent, and a candidate whose grade in either or both falls below 75 per cent is conditioned. Either or both of these conditions must be removed before the candidate is eligible for Part II. Reexamination for the removal of conditions in Part I may be taken at any regular examination after one year but within three years without additional fees. Candidates who successfully complete the Part I examinations proceed automatically to the Part II examinations held later in the year.

The written examination consists of questions on both obstetrics and gynecology, as evidence of a fundamental knowledge of both branches is required of all candidates. The fifty case records of each group B candidate must be presented with his examination paper to the local examiner. Both the written examination papers and typewritten case records will be reviewed by an examiner located in a remote district from that of the candidate.

Part II. The general oral-clinical and pathological examinations given all candidates will be conducted by the entire board at or near the time and place of the annual meeting of one or more of the national societies represented on this board, usually that of the American Medical Association. Applications must be filed at least ninety days prior to the date of examination. This examination is given to all applicants in group A and group B. The candidates will be expected to identify and discuss several obstetrical and gynecological pathologic specimens and histologic sections. An endeavor will be made to adapt the details of the oral examination to each candidate's experience and practice, and will be particularly directed to ascertain his familiarity with recent obstetrical and gynecological literature, the breadth of his clinical experience, and his general qualifications as a specialist in obstetrics and gynecology.

Examiners report orally upon each candidate to the assembled board, after which the results of their examinations are considered jointly. After a general consideration of the details of the candidate's oral and pathological examination, including a review of his capability and general adaptability, the candidate is passed or failed by the entire board. No conditions are given in Part II of the examination. When a candidate fails in Part II of the examination, he is not required to repeat Part I, but to take a reexamination in the oral, clinical, and pathological portions only.

After 1941, the distinction between candidates in group A and group B will be abolished. After that time new rulings similar to those now pertaining to group B will apply to all applicants, and every candidate will be required to undergo the written examinations and present case records (Part I), as well as the oral-clinical and pathological examinations (Part II).

CASE RECORDS

Case histories need not be copied verbatim from the hospital records but must be sufficiently complete so that the examiner can determine the diagnosis of existing conditions and evaluate the judgment of the candidate in his choice of procedure. Each history must give the hospital number and name of the hospital at which the patient was treated or operated upon, together with all pertinent dates. Histories must be typewritten on standard size paper, $8\frac{1}{2} \times 11$ inches, assembled by individual cases, and submitted without any form of binding other than light weight paper folders. The following data should be as complete as possible: essential points in history and examination; the clinical diagnosis and in operative cases preoperative diagnosis, ample summary of operative procedure; clinical and pathological diagnosis; summary of postoperative course with special reference to morbidity; findings at time of discharge from hospital and at six months "follow-up."

The obstetrical case records should show the date of the first prenatal visit and any special features bearing on the case. The examination of obstetric patients should include a routine serologic test for syphilis; also blood grouping or typing should be noted on histories of patients requiring transfusions. The weight and condition of the child at birth and at the time of discharge from the hospital should be shown on the obstetric history.

In both obstetrical and gynecological case histories not more than ten major selected nonoperative cases may be included. When pathological tissue is removed, adequate gross and microscopic descriptions are required. The candidate and the pathologist are required to employ the accepted nomenclature in the classification of gross and microscopic reports of pathological findings.

A final statement must be prepared for each case, to include an account of the candidate's personal observations of the case

both prior to and subsequent to operation. These data must include (1) the basis for the diagnosis, (2) the facts that determined the course of the treatment, and (3) critical conclusions to be drawn from the outcome of the case. Case reports which do not include such discussion and comments will not be reviewed by the examiners. Obstetrical histories which omit measurements of the pelvic inlet and outlet will be considered incomplete.

The group of histories must include a variety of material rather than a number of cases of one type. The histories should be sufficiently detailed so that the examining board, after a careful reading of the records will be able to answer the following questions:

1. Is the diagnosis warranted by the recorded data?
2. If not, how lacking?
3. Are the indications for operation clearly stated?
4. Is the technic satisfactorily described?
5. Do the results justify the procedure?
6. Do the conclusions drawn indicate a grasp of the subject?

Only those records will be credited toward the fifty which carry the candidate's personal deductions, conclusions, and comments, and these records must be diversified.

Note: Two complete index lists of these cases must accompany the records. Separate lists should be made for each individual hospital at which operations were performed. These lists must state the candidate's name, and at the head of each page the name and address of the hospital, the name of the patient, admission number, date of admission, date of operation, and date of discharge. The candidate must have these lists verified by the librarian, or preferably the superintendent, of each individual hospital from which these case records come. All verifications must be formally signed by the responsible hospital official.

Case histories are to be presented with the complete examination paper to the examiner conducting the written examination. They are not to be sent by the candidate to the secretary.

The final action of the board is based upon the candidate's professional record, training and attainments, as well as on the results of his formal examination. Any well qualified obstetrician and gynecologist should have no difficulty in obtaining the certificate, and the board is desirous of receiving applications from those to whom this applies.

Communications should be addressed to the secretary-treasurer.

AMERICAN BOARD OF OPHTHALMOLOGY

CONRAD BERENS, Chairman, New York.

WILLIAM L. BENEDICT, Vice Chairman, Rochester, Minn.

JOHN GREEN, Secretary-Treasurer, 6830 Waterman Avenue, St. Louis.

EVERETT L. GOAR, Assistant Secretary, Houston, Texas.

DANIEL B. KIRBY, New York.

CECIL S. O'BRIEN, Iowa City.

EDWARD C. ELLETT, Memphis.

GRADY E. CLAY, Atlanta.

ORIGIN, AIMS AND METHODS

In 1913 the American Ophthalmological Society, the Section on Ophthalmology of the American Medical Association, and the American Academy of Ophthalmology and Otolaryngology appointed committees to report on ophthalmic education.

In 1914 these committees recommended that medical schools of the first class establish graduate courses in ophthalmology leading to an appropriate degree, and that these courses should represent not less than two years of systematic work subsequent to taking the degree of Doctor of Medicine. There was unanimous agreement as to the need of systematized and standardized training of those who are to practice ophthalmology, but it was clear that, in the near future, the number who would take the complete course leading to such a degree would be small. Moreover, such a course would not solve the problem of differentiating, in some degree, between the competent and the incompetent among those now in practice in ophthalmology. The committees were continued and, in 1915, they made further recommendations, as a result of which a joint board was created consisting of three representatives from each of the three special societies.

In 1916, after much preliminary work, this Board was organized as the American Board for Ophthalmic Examinations (later changed to "American Board of Ophthalmology"). It was incorporated May 3, 1917.

In 1934 the plan of organization was changed so that each component society elects four members, instead of three, to form the Board. The members of this Board are chosen in the same manner as the presiding officers of these societies are chosen. One is elected each year by each of the societies represented on the Board, to serve for four years.

As other specialties formed boards similar to the American Board of Ophthalmology the need for some supervising and coordinating control led to action by the American Medical Association in 1933 authorizing the Council on Medical Education and Hospitals: (1) to formulate standards of administration, based on those of the American Board of Ophthalmology, of Otolaryngology, of Gynecology and Obstetrics, and of Dermatology and Syphilology; and (2) to recognize officially new boards meeting these standards.

The Constitution of the Advisory Board for Medical Specialties which was organized in 1934 states that: "This Board shall act in an advisory capacity to such organizations as may seek its advice concerning the coordination of the education and certification of medical specialists."

The Advisory Board adopted June 10, 1934, a list of essentials for approved special examining Boards. It is practically identical with the outline of essentials for approved specialty boards adopted June 10, 1934, by the Council on Medical Education and Hospitals and ratified June 11, 1934, by the House of Delegates of the American Medical Association to become effective after 1942.

CHIEF FUNCTIONS

1. To establish standards of fitness to practice ophthalmology cooperating with hospitals and graduate schools of medicine.

2. To arrange and conduct examinations to test the qualifications of those who practice ophthalmology, and to confer certificates upon those who meet the standards established by the Board.

3. To act as preceptors for prospective students of ophthalmology.

NO DEGREES

The conferring of a degree is left to the universities, where it belongs, and the Board makes no attempt to control the practice of ophthalmology by any license or legal regulation whatever. It simply aims to establish a standard of fitness to practice ophthalmology, and to certify any who, voluntarily, apply and satisfy the Board of their qualifications.

The following is the wording of the present certificate:

The American Board of Ophthalmology hereby certifies that(name)..... has pursued an accepted course of graduate study and clinical work, and has successfully passed the examination in ophthalmology conducted under the authority of this Board.

Date.....

Signatures of members of the Board

Many special eye hospitals as well as general hospitals in all parts of the country require the certificate for appointment or promotion on their staffs. In addition, many societies now require the certificate as a prerequisite for membership.

The number of institutions and societies which require the certificate of the Board is increasing.

The American College of Surgeons recognizes the certificate of this Board as evidence of academic fitness in ophthalmology. It requires from candidates for its Fellowship who hold such certificates only half as many case histories as from those who are not so certificated.

Up to Jan. 1, 1939, nearly 1,600 ophthalmologists have received the certificate of the Board.

FEES

The fee for the examination and the certificate of the American Board of Ophthalmology is \$50. Of this sum \$25, which is not returnable, must accompany the application. The balance of \$25 must be paid when the certificate is ready for issuance.

If a candidate fails in an examination, he may be admitted to a second examination within three years, for which there will be no additional fee.

Applications expire three years from date of application. If a candidate has not appeared for examination before expiration of his application, he will be required to apply again and pay an additional application fee of \$25.

The fees of candidates are used solely for defraying the actual expenses of the Board. The members of the Board and their associates receive no emoluments.

GENERAL REQUIREMENTS FOR ALL CANDIDATES

1. Application on special blank, which may be obtained from the Secretary, must be filled out accurately. Letters of endorsement from two well known physicians (preferably ophthalmologists) together with any other required credentials must accompany the application and must be sent to the Secretary at least ninety days before the candidate expects to appear before the Board.

2. The candidate must have high ethical and professional standing in his community.

3. Membership in the American Medical Association or such other societies as are recognized for the purpose by the Council on Medical Education and Hospitals of the American Medical Association. In the case of an applicant whose training has been received outside of the United States and Canada, his credentials must be satisfactory to the Board; if he has been in practice less than ten years he should obtain the certificate of the National Board of Medical Examiners.

4. A list of papers or books published by the candidate must be submitted.

5. Reports of ten cases of varied character which have been observed and treated by the applicant are required.

6. An examination divided into Part I (written) and Part II (clinical, practical and laboratory). In both of these examinations a knowledge of the practical application of the basic sciences of ophthalmology will be required.

7. Citizenship in country where candidate practices.

The final action of the Board is based on the candidate's professional record, training and attainments as well as on the results of his formal examinations.

GENERAL EDUCATIONAL REQUIREMENTS

(Applicable as far as possible after 1942)

1. A degree from a medical school of high standing satisfactory to the Board and approved by the Council on Medical Education and Hospitals of the American Medical Association. In the case of an applicant whose training has been received outside of the United States and Canada, his credentials must be satisfactory to this Board. He may be required to obtain the certificate of the National Board of Medical Examiners.

2. Completion of an internship of not less than one year in a hospital approved by the same Council.

SPECIAL TRAINING

(Applicable as far as possible after 1942)

A period of combined study, training and practice of not less than three years in approved medical schools, hospitals, clinics, dispensaries, laboratories, preceptorships and private practice.

(A total of five years will be required of candidates practicing eye, ear, nose and throat.)

1. This shall include graduate study of the basic medical sciences which are fundamental to the intelligent practice of ophthalmology, particularly: anatomy, histology, embryology, optics, physiologic optics, visual physiology and psychology, pathology, bacteriology, pharmacology. Mere factual knowledge of these subjects is not sufficient. The candidate must have had training in their application and in their use in clinical ophthalmology, especially in refraction, disorders of motility and binocular vision, perimetry, and in the skilful adjustment and use of instruments such as the ophthalmoscope, retinoscope, slit lamp and microscope.

2. Active clinical experience in approved hospitals, clinics, dispensaries and private practice. Library and laboratory facilities should be utilized for the intensive study of cases.

The subject matter to be covered under 1 and 2 is outlined in the syllabus prepared by the Board.

These requirements may be met in various ways:

BASIC STUDIES

A—By courses in approved graduate medical schools.

B—By the opportunities for study afforded by the appointment to a junior position in one of the departments with attendance at advanced lectures in the other subjects.

C—By advanced study of these subjects while a resident and by application of the principles involved to patients under one's control.

D—By the detailed study, under supervision or as assistant to an experienced research worker, of some problem or topic which brings the basic facts of physiology, pathology, etc., into direct relation with the concrete clinical problem. The analysis of a problem with detailed knowledge of its fundamental physiologic and pathologic background does much to stimulate thoroughness, clear thinking and progress.

CLINICAL EXPERIENCE

A—By residency in an approved hospital. The most desirable of these residencies have regular lectures covering the whole field of clinical ophthalmology and of the basic subjects as applied in clinical practice. Many of these have seminars at which residents report cases which they have carefully worked up. These are discussed by the other residents and by the staff and the method of presentation as well as the subject matter critically considered.

B—There are many residencies, usually of 12 months, which do not furnish regular instruction by lectures and quizzes and seminars. If he has access to a good library and laboratory, the student can learn a great deal and has some advantages over the man who expects to be "spoon-fed." The syllabus prepared by the Board will guide him in his selection of topics to be studied.

C—There are some opportunities to continue the study and experience by securing appointments as Fellows.

D—By a period of training in association with a well trained and critical ophthalmologist who takes the trouble to teach and guide his assistant.

E—After completing a residency it is of great advantage to secure a position in a clinic as fellow or assistant. This may require only part time work, but due credit will be given. Its value to the student depends on how much study he puts into it and on how competent his seniors are.

F—Research under competent critical and sympathetic supervision will give first hand insight into (1) the methods whereby old knowledge was and new knowledge is acquired, and (2) the pitfalls which accompany attempts to enlarge the sphere of knowledge. Only in this way can the candidate evaluate facts of the past and present in the intelligent critical way which is expected of the specialist.

The candidate who cannot secure the type of residency he desires should not despair, for his progress depends far more on how he uses his opportunities than on the opportunities themselves.

WHAT CONSTITUTES THE EXAMINATION

In determining the question of certification, the examiners rely on the following criteria:

1. The applicant's professional record;
2. The applicant's case reports;
3. A written examination;
4. A practical clinical and laboratory examination.

CASE REPORTS

Detailed instructions for the preparation of case reports should be obtained from the Secretary.

WRITTEN EXAMINATION: PART I

The written examination may be given simultaneously in as many cities as the Board may determine suitable for the purpose. A candidate, to be eligible for Part I, must meet all general requirements. Arrangements will be made for candidates to report in a convenient city where there may be a Board member, or an Associate member, to conduct and supervise the written examination.

These examinations will not be given at the time of the oral and clinical examinations or Board sessions but will be held at least sixty days before such examinations simultaneously in different parts of the country at places reasonably convenient to candidates.

No candidates shall be eligible for the practical examination until he has passed the written examination and his case reports have been found satisfactory. In the event of failure in either or both of these preliminary tests, a candidate is conditioned and the conditions must be removed before the candidate is eligible to appear for the practical (Part II) examination.

The written examination questions will be on all subjects as follows:

External Diseases.	Perimetry and Campimetry
Ophthalmoscopy	Relation of the Eye to General
Pathology-Histopathology	Diseases
Refraction and Retinoscopy	Therapeutics and Operations
Anatomy and Embryology	(including Practical Surgery)
Ocular Motility	Optics and Visual Physiology

Written examination papers will be reviewed by examiners who reside in districts remote from those in which the candidate practices.

PRACTICAL AND CLINICAL EXAMINATION: PART II

The purpose of the examination is to determine the competence of the candidate to practice ophthalmology.

Candidates must be prepared to be examined in the whole field covered by the syllabus of the Board. The time spent in preparation will count less than the knowledge and experience acquired as shown on examination.

The subdivisions of the practical examination are as follows:

1. External diseases of the eye, lacrimal passages, etc., including inspection, focal illumination, use of loupe and slit lamp, examination of reactions of the pupil, of tension by tonometer and by fingers.

2. Ophthalmoscopy. Several patients will be examined by the candidate and the findings described or drawn. The ability to see with the ophthalmoscope and to interpret what is seen, and the systematic and thorough methods of examination used by the candidate will count for more than mere statement of diagnosis. A candidate should bring his own ophthalmoscope so that he may not suffer the handicap of an unfamiliar instrument.

3. Pathology. The candidate should be familiar with general clinical pathology as well as the etiology, pathology, and bacteriology of diseases of the eye. He will be asked to examine microscopic slides and to recognize ordinary normal and pathologic histology of the eye and to identify the commoner microorganisms.

4. Refraction. A candidate will examine patients and show mastery of various methods, and of the principles of refraction and of retinoscopy. He should bring his own retinoscope.

5. Ocular Motility. The candidate will demonstrate upon patients his familiarity with routine methods of examination for abnormalities of the ocular muscles.

6. Practical Surgery. A candidate will demonstrate his surgical technic upon animals' eyes. To have the advantage of using instruments with which he is familiar, he should bring his own equipment for performing a regular combined extraction of the lens.

DATES OF PART II EXAMINATION

Examinations will be held annually at or near the time and place of the meeting of the American Medical Association; also at other times and places at the discretion of the Board, depending on the number of applications from any region.

Notices of all examinations will be found in The Journal of the American Medical Association, and in the special journals of ophthalmology.

REEXAMINATION

Candidates may be reexamined as often as they desire, provided they give satisfactory evidence of adequate preparation. Six months must elapse between examinations and the Board may, at its discretion, deny the candidate the privilege of reexamination.

REVOCATION OF CERTIFICATE

Any certificate issued by the Board shall be subject to revocation by the Board at any time in case it shall determine in its sole judgment that a candidate, who has received the certificate of the American Board of Ophthalmology, either was not properly qualified to receive it, or has since its receipt become disqualified.

PREPARATORY GROUP

In establishing a Preparatory Group of prospective candidates for its certificate, the American Board of Ophthalmology plans to assist physicians who wish to study ophthalmology so that they will be acceptable as candidates for examination and certification when they have completed the requirements.

Any graduate or undergraduate of an approved medical school is eligible to make application for membership in this group. Candidates so applying will be notified officially by the secretary when the Board has accepted their applications. If accepted, data will be sent concerning ethical and educational requirements. Syllabuses and other information will be made available to them. The Board desires to help candidates improve their opportunities so that they will be fully prepared for the examination.

It is essential that candidates conduct themselves in an entirely ethical manner to the end that they bring honor to the profession.

Information and counsel will be available at all times to accepted candidates in this group through advisers who are members or past members of the Board.

Members of the Preparatory Group must keep a summarized record of their activities, two copies of which will be sent to the Secretary in January of each year and will be incorporated in the final application for examination and certification.

The fee for application for membership in the Preparatory Group is \$10. This will be deducted from the \$50 which is required of every candidate for examination. When the candidate makes application for the examination, he will be required to pay \$25, and the balance of \$15 must be paid when the certificate is issued. No fees will be refunded.

It is of increasing importance that a physician specializing in diseases of the eye obtain the certificate of the American Board of Ophthalmology. The American Medical Association will especially designate certificated ophthalmologists in future directories. A special directory of all certificated specialists will be published by the Advisory Board for Medical Specialties.

Many national and local ophthalmologic societies demand the certificate of the American Board of Ophthalmology before admission. Promotion in many hospitals cannot be obtained unless the applicant holds the certificate of the Board.

For sufficient reason, a person enrolled in this Preparatory Group may be dropped by vote of the Board.

Communications should be addressed to the secretary.

PHILIP D. WILSON, New York City.

INTRODUCTION

The rapid growth of specialization and the increasing number of physicians limiting themselves in their practice to one branch of medicine or surgery emphasize the need for the proper certification of specialists in the various branches of the medical science. In recognition of this condition the American Board of Orthopaedic Surgery, Inc., aims to elevate the standard of qualifications for the practice of orthopaedic surgery and to certify those surgeons who voluntarily comply with its requirements.

In order to place orthopaedic surgery on the highest possible plane, the American Orthopaedic Association, the Section on Orthopaedic Surgery of the American Medical Association and the American Academy of Orthopaedic Surgeons united in organizing a certifying board which was incorporated in the year 1934 as the American Board of Orthopaedic Surgery, Inc.

The American Board of Orthopaedic Surgery, Inc., has been officially approved by the Advisory Board for Medical Specialties and by the Council on Medical Education and Hospitals of the American Medical Association.

WHAT THE BOARD WILL ACCOMPLISH

1. Certification by the Board will establish a criterion to both interested lay and professional groups for judging the qualifications of an orthopaedic surgeon. Thus a reliable guide will be furnished for the choosing of consultants.

2. Hospitals and other organizations will no doubt establish rules limiting service on their permanent staffs to those certified by the Board.

3. It will gradually tend to limit the practice of orthopaedic surgery to those properly qualified.

4. Certification by the American Board of Orthopaedic Surgery is one of the essential requirements for membership in the American Orthopaedic Association and the American Academy of Orthopaedic Surgeons.

Excerpts from Articles 1, 2, 7 and 8 of the By-Laws.

Article 1. *Section 1. DEFINITION.* Orthopaedic Surgery is that branch of surgery especially concerned with the preservation and restoration of the functions of the skeletal system, its articulations and associated structures.

Article 2. *Section 2. PURPOSES.* To test and determine the qualifications of applicants for registration and to issue certificates to those found qualified.

Section 3. To prepare and maintain a registry of the holders of the certificates issued by the Board.

Section 4. To serve the public, physicians, hospitals and medical schools by furnishing lists of those who have received the certificate of the Board, and thus to assist in protecting the public against irresponsible and unqualified practitioners who profess to specialize in orthopaedic surgery.

Article 7. *Section 1. APPLICATION FOR CERTIFICATE.* Each application for a certificate shall be filed with the secretary upon the prescribed form; and shall be accompanied by the fee which the Board may fix from time to time. It shall also be accompanied by an unmounted autographed recent photograph of the applicant and the names of two orthopaedic surgeons acceptable to the Board, who may be referred to for information in regard to the applicant.

Section 2. The applicant must have the following qualifications:

(a) He must be a graduate of a medical school approved by the Council on Medical Education and Hospitals of the American Medical Association.

(b) He must be of high ethical and professional standing.

(c) He must be a citizen of the United States or Canada.

(d) He must be duly authorized to practice medicine in the state or province of his residence.

(e) He must be a member of the American Medical Association or another society approved by the Council on Medical Education and Hospitals of the American Medical Association.

(f) He must have had one year of internship in a general hospital acceptable to the Board.

(g) After Jan. 1, 1940, he must have had three years of concentrated instruction in orthopaedic surgery approved by and acceptable to the Board. (A residency of at least two years on an orthopaedic service of a hospital recognized by the Council of the American Medical Association is desirable.)

(h) He must have knowledge of the basic medical sciences related to orthopaedic surgery.

(i) He must have had at least two years' further experience in the actual practice of orthopaedic surgery. Continuation of training (g) beyond the three years required will not be considered as actual practice unless the position of the candidate is considered permanent or his responsibilities equivalent to those encountered in private practice. This means that interns, residents, fellows, graduate students and assistants will not be credited with additional periods of training unless they are permanent members of the organizations with which they are associated.

(j) He must have limited his work to the field of orthopaedic surgery for at least two years prior to the submission of his application for examination.

(k) In the case of an applicant whose training has been received outside of the United States and Canada, his credentials must be satisfactory to the Council on Medical Education and Hospitals of the American Medical Association and to the National Board of Medical Examiners. In addition, he must have been engaged in the practice of orthopaedic surgery in the United States (or Canada) for at least three years prior to the submission of his application.

Section 3. Each applicant shall be examined and his qualifications determined by the Board in such manner as it may designate, and his record shall be reviewed by the Board in the light of all assembled information.

Article 8. *Section 1. CERTIFICATE.* If the applicant be found qualified therefor, a certificate that he has been found by this Board qualified to practice orthopaedic surgery shall be issued to him. The certificate shall be in such form as may be adopted by the Board, and shall be signed by the officers and members of the Board.

EXAMINATION

Examinations will be held once or twice a year. If feasible, these examinations will be in conjunction with meetings of the major orthopaedic societies.

Oral and written examinations will be held on clinical, anatomical and pathological phases of orthopaedic surgery. Anatomical and pathological laboratories and hospital wards will be used when practicable.

APPLICATION FOR CERTIFICATION

Application forms may be obtained from the Secretary of the Board. These should be filled in accurately and returned not less than ninety days prior to the next examination. An autographed photograph and the fee must accompany the application.

FEES

A fee of \$50 must accompany the completed application form. This fee will be returned only in the cases of candidates found ineligible for examination. Address communications to the secretary-treasurer.

AMERICAN BOARD OF OTOLARYNGOLOGY

HARRIS P. MOSHER, President, Boston.
BURT R. SHURLY, Vice President, Detroit.
WILLIAM P. WHERRY, Secretary-Treasurer, 107 South 17th
St., Omaha.

BOARD OF DIRECTORS

HARRIS P. MOSHER, Boston.
BURT R. SHURLY, Detroit.
WILLIAM P. WHERRY, Omaha.
JOSEPH C. BECK, Chicago.
THOMAS E. CARMODY, Denver.
GEORGE M. COATES, Philadelphia.
LEE W. DEAN, St. Louis.
RALPH A. FENTON, Portland, Ore.
THOMAS J. HARRIS, New York.
JOHN J. SHEA, Memphis, Tenn.

ASSISTANTS TO THE BOARD

A. C. FURSTENBERG, Ann Arbor, Mich.
PERRY G. GOLDSMITH, Toronto, Canada.
W. E. GROVE, Milwaukee.

E. M. SEYDELL, Wichita, Kan.

HONORARY MEMBERS

THOMAS H. HALSTED, Syracuse, N. Y.
GEORGE E. SHAMBAUGH, Chicago.
FRANK R. SPENCER, Boulder, Colo.

ORIGIN, AIMS AND METHODS

SOURCE OF AUTHORITY

In 1924 the American Otological Society, the American Laryngological Association, the American Laryngological, Rhinological and Otological Society, the American Academy of Ophthalmology and Otolaryngology, and the Section on Laryngology, Otology and Rhinology of the American Medical Association, each appointed two members, making a total of ten members, to constitute the first American Board of Otolaryngology. These appointments were made at the request of Dr. George E. Shambaugh of Chicago, whose persistent efforts resulted in the establishment of the Board.

Dr. T. H. Halsted of Syracuse, New York, and Dr. H. W. Loeb of St. Louis were appointed to represent the American Otological Society; Dr. H. P. Mosher of Boston and Dr. R. H. Skillern of Philadelphia were appointed to represent the American Laryngological Association; Dr. B. R. Shurlay of Detroit and Dr. F. R. Spencer of Boulder, Colorado, to represent the American Laryngological, Rhinological and Otological Society; Dr. T. E. Carmody of Denver and Dr. W. P. Wherry of Omaha to represent the American Academy of Ophthalmology and Otolaryngology; and, Dr. J. C. Beck of Chicago and Dr. R. C. Lynch of New Orleans to represent the Section on Laryngology, Otology and Rhinology of the American Medical Association.

CHIEF ACTIVITIES OF THE BOARD

First. To establish standards of fitness to practice otolaryngology.

Second. To arrange, control and conduct examinations to test the qualifications of those who desire to practice Otolaryngology and to confer a certificate upon those who meet the established standards.

These activities proceed from the object of the Corporation which is stated in the Articles of Incorporation to be:

"The object of the corporation shall be to elevate the standard of otolaryngology, to familiarize the public with its aims and ideals, to protect the public against irresponsible and unqualified practitioners, to receive applications for examination in otolaryngology, to conduct examinations of applicants, to issue certificates of qualification in otolaryngology and to perform such duties as will advance the cause of otolaryngology."

NO DEGREES

The conferring of a degree is left to the universities, where it belongs, and the Board makes no attempt to control the practice of otolaryngology by efforts to promote any license or

legal regulation whatever. It simply aims to establish a standard of fitness to practice otolaryngology, and to certificate those who voluntarily apply and satisfy the Board of their qualification.

VALUE OF CERTIFICATE

The five National Otolaryngological Associations responsible for the organization of the Board are sponsoring its activities. Four of these associations require the Board certificate from each applicant for membership.

Other important societies and organizations are following the example of these influential organizations. Moreover, the certificate of the Board is required of candidates for appointments in many and various important positions in hospitals, colleges, etc. It is expected that the medical public and the lay public will learn to discriminate between those who are well fitted and those who are not, and will be influenced by the certificate of the Board in arriving at their conclusions.

POINT OF VIEW OF EXAMINERS

Examinations are designed to test the candidate's fitness to practice otolaryngology, and will be conducted in a thorough manner. Yet it will be the aim of the examiners to be broad-minded, avoiding on the one hand an unduly exacting standard above present available facilities for preparation to practice otolaryngology, and, on the other hand, a laxity which would defeat the whole purpose. Thus an older practitioner may not be minutely versed in certain of the newer details of anatomy, physiology, pathology, etc., which he may once have known, yet his grasp of the science and art of otolaryngology, and his fitness and competence to practice may be of a high order.

On the other hand, to expect and to demand of the recent graduate the mature, well balanced judgment and sagacity of the older practitioner, would be equally unfair. The examination will be adapted to both classes.

This movement is undertaken for the purpose of raising the standard of otolaryngology. Whenever applicants fail to pass the examination, it will be the desire of the Board to induce such men to make an effort to overcome their deficiencies, and the Board will gladly, when requested, make suggestions as to what courses should be pursued by such applicants to enable them to establish their fitness.

CLASSIFICATION OF CANDIDATES

Applicants for examination and for the Certificate of the Board are divided into classes according to the length of time they have practiced otolaryngology.

(Limited practice in otolaryngology interpreted as 90% Otolaryngological practice—Ophthalmology excepted.)

Class I—Limited Practice—15 years or more.

Class II—Limited Practice—10 to 15 years.

Class III—Limited Practice—5 to 10 years.

Class IVA—Limited Practice—5 years.

Class IVB—Limited Practice—3 and 4 years.

(Candidates having completed a satisfactory residency or an acceptable full academic year basic science course.)

REQUIREMENTS

UNTIL JAN. 1, 1942

The following general requirements are demanded by the board:

First. A candidate acceptable for the examination must be a graduate from a school approved by the Council on Medical Education and Hospitals of the American Medical Association; furthermore, he must have at least one year of internship in an approved hospital.

Second. Membership in the American Medical Association or, by courtesy, membership in such Canadian or other medical societies as are recognized for this purpose by the Council on Medical Education and Hospitals of the American Medical Association. Except as here provided, membership in other societies should not be required.

Third. In addition, a candidate must have completed at least three years graduate preparation for the specialty, at least one year (more desirably two) in a recognized residency or in basic courses and followed by private practice in otolaryngology.

Fourth. Five years of specialized practice will be accepted in lieu of the requirements of paragraph 2 until Jan. 1, 1941.

Fifth. Application must be made on a special blank procured from the Secretary. It must be executed and returned to the Secretary, together with other required credentials sixty days in advance of the examination at which the candidate desires to appear.

Sixth. All applicants must send a small photograph with application and must present themselves in person before the Board.

Seventh. Fee for the examination is \$50 and same must accompany application blank. No application will receive consideration until fee is paid.

Eighth. An application remains valid only five years—therefore, an applicant must appear for examination within this time or forfeit fee. The fee under no circumstances is returnable.

If the candidate fails in an examination he will be admitted to a second examination after one year, but within the regulation time limit of his application. Sixty days' notice of intention to appear is required. If a candidate who has failed does not appear before the expiration of validity of his application he will be required to make new application and pay additional fee of \$50 before reexamination.

An applicant having failed twice, must file a new application, pay an additional fee of \$50 and convince the Board of additional postgraduate study previous to being assigned appointment for another examination.

Examinations covering two days will be held bi-annually at, or near, the time and place of meeting of the American Medical Association, and of the American Academy of Ophthalmology and Otolaryngology.

An extra examination is sometimes held provided the class of applicants is large enough to warrant it.

Candidates are required to sign the following pledge:

I hereby apply to the American Board of Otolaryngology for examination by the said board in accordance with its rules and herewith enclose the fee of fifty dollars. I hereby agree that prior to an examination, or subsequent to my examination, the board may investigate my standing and reputation as a physician, including my reputation for complying with the standard of ethics of the profession, and may refuse to examine me, or, having examined me, may refuse a certificate, and such refusal to grant a certificate, whether justified or otherwise, may not and shall not be questioned by me in any court of law or equity or other tribunal, nor shall I have any claim, in the event of such refusal, to a return of the fee accompanying this application.

PRACTICAL EXAMINATION

1—Written examinations:

Detail Anatomy—Class IVA, Class IVB.

Regional Anatomy—Class III.

2—Pathology:

Microscopy—Class IVA, Class IVB.

Gross—Class III.

3—Clinical examination of patients: To include history taking; physical and functional examinations; use of laboratory and x-ray findings; discussion of differential diagnosis; and discussion and defense of his findings, opinion and suggested management.

All classes.

4—Didactic examination to be a private, oral examination covering any aspect of otolaryngology and its interrelation with general medicine.

All classes.

Communications should be addressed to the secretary.

AMERICAN BOARD OF PATHOLOGY, Inc.

A. H. SANFORD, President, Rochester, Minn.

FREDERICK H. LAMB, Vice President, Davenport, Iowa.

FRANK W. HARTMAN, Secretary-Treasurer, 2799 W. Grand Blvd., Detroit.

ALVIN G. FOORD, Pasadena, Calif.

HOWARD T. KARSNER, Cleveland.

ROY R. KRACKE, Emory University, Ga.

E. B. KRUMBHAR, Philadelphia.

J. J. MOORE, Chicago.

ORGANIZATION

In June 1935 the Section on Pathology and Physiology of the American Medical Association and the American Society of Clinical Pathologists appointed committees which acted jointly in consideration of the feasibility and necessity of a national qualifying board. The joint committees agreed unanimously that such a board should be established and proceeded to draw up by-laws for such a board. In May 1936 the American Society of Clinical Pathologists and the Section on Pathology and Physiology of the American Medical Association accepted the proposed by-laws, authorized the nomination of four members each to the board and suggested incorporation in the state of Michigan. Approval of the Board by the Advisory Board for Medical Specialties and the Council on Medical Education and Hospitals of the A. M. A. was given. On July 19, 1936, the organization of the Board was carried out in Chicago. The officers of the Board, elected at this meeting, were:

A. H. Sanford, President.

Frederick H. Lamb, Vice President.

F. W. Hartman, Secretary-Treasurer.

Dr. Karsner of the A. M. A. Section and Dr. Foord of the A. S. C. P., whose terms on the Board expired in 1938, were renominated by their respective organizations and were reelected by the Board. The president, vice president and secretary-treasurer were also reelected for 1938-1939.

PURPOSES

A. To encourage the study and promote the practice of pathology.

B. To elevate the standards and advance the cause of pathology, by encouraging its study and improving its practice.

C. To determine the competence of those wishing to practice this specialty of pathology and to arrange, conduct, and control investigations and examinations to determine the qualifications of such individuals who voluntarily apply for the certificates issued by the corporation.

D. To grant and issue certificates in the special field of pathology to voluntary applicants therefor and to maintain a registry of holders of such certificates.

E. To serve the public, the medical profession, hospitals, and medical schools by preparing and furnishing lists of specialists who have been certified by the corporation.

VALUE OF THE CERTIFICATE

Judging from the experience of other specialties operating a certifying board it is anticipated that the certificate will be of value in that the medical profession, the lay public, and hospital administrators will utilize certificates from the Board as a means of discriminating between those that are thoroughly qualified in pathology and those that are not. Lists of those holding certificates will be made available from time to time by this Board through the publication of the same in pamphlets and in national medical journals.

BOARD NOT AN EDUCATIONAL INSTITUTION

The Board is in no sense an educational institution and the certificates of the Board are not to be considered degrees. Therefore the certificate does not confer on any person legal qualifications, privileges, or license to practice medicine or the specialty of pathology. The Board does not purport in any way to interfere with or limit the professional activities of any licensed physician. Its chief aim, as stated above, is to standardize the qualifications for the specialty of pathology and to issue certificates to those voluntarily complying with the requirements of the Board.

GENERAL REQUIREMENTS

A. General qualifications.

1. Satisfactory moral and ethical standing in the profession.

2. License to practice medicine.

3. Membership or associate membership in the American Medical Association or by courtesy membership in such Canadian or other national medical societies as are approved by the Council on Medical Education and Hospitals of the American Medical Association.

4. That the applicant devotes his time primarily and principally to the practice of pathology.

B. Professional education.*

1. Graduation from a medical school in the United States or Canada, approved by the Council on Medical Education and Hospitals of the American Medical Association.

C. Special training, to be effective after July 1, 1938:

1. Completion of an internship of not less than one year in a hospital approved by the Council on Medical Education and Hospitals of the American Medical Association.

2. A period of study, exclusive of internship, of not less than three calendar years, exclusive of reasonable vacation periods, in an institution or department of pathology recognized by the same Council and the Board of Trustees as competent to provide a satisfactory training in the field of pathology. This period of special training preparation shall include the following:

(a) Graduate training for one year in the various phases of clinical pathology.

(b) Training and experience of not less than two years in a department of pathologic anatomy.

(c) Such training may be combined or in sequence.

3. A fifth year of training or practice in pathology.

D. Special qualifications:

1. The board may accept candidates without special training as outlined in Section C above provided that:

(a) The candidate shall have been for a period of five years of professorial rank in a department of pathology in an approved medical school, or

* NOTE: In case of an applicant whose education and/or training has been received outside the United States or Canada, his credentials must be acceptable to the National Board of Medical Examiners and the American Board of Pathology.

MEDICAL EDUCATION

813

(b) The candidate shall have been practicing pathology for ten years in a senior position in a hospital, having an adequate department of pathology, and approved by the Council on Medical Education and Hospitals of the American Medical Association.

Candidates with special qualifications, as outlined in Section D above, may be certified without examination, at the discretion of the Board.

APPLICATION BLANK AND FEE

Application must be made on the special form which may be procured from the secretary and forwarded with other required credentials and the application fee. Applications cannot be given consideration by the Board unless accompanied by the application fee.

The application or examination fee for candidates is \$35. If the candidate fails in his examination he will be refunded a second examination after one year, but not later than three years, without additional fee. After two reexaminations the applicant must file a new application and pay an additional fee before a fourth examination will be given.

The examination fee of \$35 has been arrived at after careful consideration, and is based on actual estimates of the expense of examination and administration. None of the Board members receive any compensation for their services except actual expenses incurred.

If the applicant, for any reason, is deemed ineligible for examination by the Board his fee will be returned; however, the application fee is not returnable after the candidate has officially been accepted for examination and notified to report for the same.

EXAMINATIONS

Written and oral examinations will be held at or near the time and place of national meetings at the discretion of the Board. If a number of applications from any region of the country are received an examination in conjunction with a national medical meeting in that section will be arranged so that the financial outlay of the applicant in meeting the examinations will be as small as possible.

The examinations are to be based on the broad principles of pathology with emphasis on diagnosis and interpretation. The applicant may apply for certification in either pathologic anatomy or clinical pathology, or both. These general subjects have been defined in the by-laws as follows:

1. Pathologic anatomy is that branch of pathology which deals with the morphological aspects of disease, recognition being given that this definition covers two phases of pathology.
 - (a) The applied phase, with special attention to biopsy description and diagnosis.
 - (b) The academic phase of teaching and general morphology.
2. Clinical pathology is that branch of pathology which deals with bacteriology, immunology, biochemistry, parasitology, hematology, and clinical microscopy, in relation to the diagnosis, prognosis, and treatment of clinical disease.

All communications should be addressed to the secretary-treasurer.

AMERICAN BOARD OF PEDIATRICS, Inc.

BORDEN S. VEEDER, President, St. Louis.
HENRY F. HELMHOLTZ, Vice President, Rochester, Minn.
C. ANDERSON ALDRICH, Secretary-Treasurer, 723 Elm St., Winnetka, Ill.
HORTON CASPARIS, Nashville, Tenn.
FRANKLIN PAUL GENGEBACH, Denver.
EDWARD BYER SHAW, San Francisco.
HAROLD COE STUART, Boston.
PHILIP VAN INGEN, New York.
ALFRED AUGUSTUS WALKER, Birmingham, Ala.

ORIGIN

The American Board of Pediatrics was established in June 1933 by joint action of the American Pediatric Society, the American Academy of Pediatrics and the Section on Pediatrics of the American Medical Association after consideration of the report of a committee on pediatrics as a special field of medical practice. The committee recommended that the certification plan adopted and in use in the fields of ophthalmology, otolaryngology, gynecology and obstetrics, and dermatology be adapted to pediatrics. Similar boards have been subsequently formed in all the other special fields.

In order to correlate the activities of the various qualifying boards there has been formed the Advisory Board on Medical Specialties, composed of representatives of all the qualifying

boards, including the American Board of Pediatrics, as well as representatives of the Association of American Medical Colleges, the National Board of Medical Examiners, the Federation of State Medical Boards of the U. S. A. and the American Hospital Association.

Any method of certification in any specialty must be national in scope, must in its ultimate analysis be controlled by the men in each special field and must be independent of society membership or affiliation. The American Board of Pediatrics fulfills these three essentials: A uniform standard of competency is set up, the character of which is assured through the affiliation with the Advisory Board on Medical Specialties; the board is controlled by pediatricians, its membership being composed of three men appointed by each of the three national pediatric societies; the board is not a medical society, however, and certification is independent of society affiliation.

FUNCTION

The functions of the board are outlined in the articles of incorporation as follows:

"To encourage the study, improve the practice and elevate the standards of pediatrics; and to grant and issue to physicians, duly licensed by law, certificates or other equivalent recognition of special knowledge in pediatrics."

The board has interpreted this to mean that its efforts to encourage and improve the practice of pediatrics shall be limited to its function of certification of competency in the specialty. Obviously other organizations are better able to further the general improvements in pediatrics.

1. To establish standards by which the competency of men to practice pediatrics may be estimated.
2. To arrange, control and conduct examinations to test the qualifications of those desiring certification as pediatricians.
3. To grant certificates of certification to those applicants who meet the standards successfully.

The board further feels that in carrying out these activities it is merely acting as the agent of the three societies which appointed its members and initiated the project. No financial recompense of any kind is made to any member of this board except to cover actual traveling expenses to meetings and examinations. The \$30 fee is fixed below that of any of the similar examining boards of other specialties. In the light of experience of the existing boards it may later be necessary to raise this fee to carry on the work of the board successfully.

CERTIFICATE—NOT A DEGREE

Certificates granted are in no sense degrees, nor do they purport to confer upon any person any legal qualification, privilege or license to practice pediatrics. Neither does the board intend in any way to limit the activities of any licensed physician. It is merely attempting to standardize qualifications and to issue certificates to those who voluntarily comply with the requirements.

VALUE OF THE CERTIFICATE

It is anticipated that the certificate will become of value in that both the medical and lay public, including hospital directors, will soon utilize the certificate from this board as a means of discriminating between those who are well grounded as pediatricians and those who are not.

A certificate is required as one of the qualifications for new members of the American Academy of Pediatrics. The certificate of the American Board of Pediatrics is recognized by the Council on Medical Education of Pediatrics and the American Medical Association. Holders of certificates are so designated in the directory of the American Medical Association.

Lists of those holding certificates will be published by this board from time to time. Such lists will also be published in the leading pediatric journals of the country.

APPLICANTS FOR CERTIFICATES

Requirements for Applicants.—Each applicant for a certificate must establish in a manner satisfactory to the board that, he is of high ethical and professional standing, is a graduate of a medical school which is satisfactory to the board, and has received adequate training in pediatrics as a specialty, in addition to passing the examination given by this board.

Applicants will be divided into two classes, according to the length of time they have been engaged in the specialty. Following is the classification of applicants for certification. The changes are based upon the experience gained from examination and upon the general requirements as adopted by the Advisory Board of Medical Specialties and the Council on Medical Education and Hospitals of the American Medical Association.

Group I.—Physicians who have specialized in pediatrics for ten years or more. After July 1, 1943, Group I will be abolished.

The minimum requirements for *Group II* are as follows: Graduate of a Class A medical school.

One year's intern service in a recognized hospital.

Two years' service in a pediatric center.*

An additional term of two years of specialized study and/or practice.

The board defines service in a pediatric center as full time devoted to rounded experience in an acceptable hospital or a graduate course, which includes ward and outpatient service and both therapeutic and preventive pediatrics. The time served in pediatric centers need not be continuous or spent in the same institution. In the case of a post-graduate course an academic year will meet the requirement of one year's work.

The application fee is \$30 and must be remitted with the application. Refund will be made only if the applicant is refused examination. The applicant who has failed in an examination will not be required to pay a second fee if he takes another examination after the lapse of two years.

Application must be made on special blanks which may be secured from the secretary. These must be sent to the secretary at least four months before the date at which the candidate expects to take the examinations.

Letters from two competent pediatricians recommending each applicant must be sent to the secretary of the board. These letters are not to accompany the application, but should be sent directly to the secretary. No member of the board may recommend any applicant.

INFORMATION CONCERNING EXAMINATIONS

Examinations will be held at or near the time and place of meetings of the American Medical Association and of the American Academy of Pediatrics, or at other times and places at the discretion of the board, depending on the number of applicants from any region of the country. It is proposed to arrange examinations in different cities so that as little financial burden as possible will be placed upon the applicants in meeting the examiners.

The purpose of these examinations is to determine the applicant's competency to practice pediatrics. This board feels that the best impression of an applicant's ability can be obtained by oral examination although written ones may be substituted at times. It is not proposed at the present time to require the applicant to send in case reports. The board feels that growth and development are fundamental parts of pediatric training.†

A list of papers or books published must be sent with the application blank.

Further information as to the scope of the examinations will be published as soon as available. It should be emphasized that competency in the practice rather than in the theory of pediatrics is required.

Communications should be addressed to the secretary.

HISTORY AND STATEMENT OF PRINCIPLES

The American Board of Psychiatry and Neurology was founded in 1934 following conferences of committees appointed by the American Psychiatric Association, the American Neurological Association, and the Section on Nervous and Mental Diseases of the American Medical Association. This action was taken in response to a widespread desire among specialists in psychiatry and neurology for some means of distinguishing the fully qualified specialist from the would-be specialist of inferior training and inadequate experience. That this desire is by no means limited to those who practice psychiatry and neu-

rology is indicated by the formation of corresponding boards covering internal medicine, surgery, and the major specialties. The success of this method of distinguishing the specialists is indicated by the increasing number of candidates taking the examinations, and by the listing accorded in the American Medical Directory to those specialists holding the certificates of the various boards.

CONSTITUTION AND ACTIVITIES

The American Board of Psychiatry and Neurology is composed of twelve members, four each from the American Neurological Association and from the American Psychiatric Association and two neurologists and two psychiatrists elected by the Section on Nervous and Mental Diseases of the American Medical Association. Annual elections to fill the places of members whose terms have expired take place in each of the nominating associations with the understanding that neurology and psychiatry are always equally represented on the board. The board holds annual meetings in December of each year for the transaction of whatever business may come before it and also holds special meetings for the purpose of examining candidates and of passing upon the qualifications of those seeking the certificate without examination.

FUNCTIONS

(a) To determine the competence of specialists in psychiatry and neurology.

(b) To arrange, control and conduct investigations and examinations to test the qualifications of voluntary candidates for certificates issued by the Board.

(c) To grant and issue certificates or other recognition of special knowledge in the field of psychiatry and neurology to successful voluntary applicants therefor.

(d) To serve the public, physicians, hospitals and medical schools by preparing lists of practitioners who shall have been certified by the Board.

(e) To consider and advise as to any course of study and technical training, and to diffuse any information calculated to promote and ensure the fitness of persons desirous of qualifying for a certificate of qualification to be issued thereby.

INFORMATION FOR APPLICANTS

EXCERPTS FROM ARTICLE VII OF THE BY-LAWS

SECTION 1. Application for Certificates. Application for certificates shall be considered by the secretary only when made formally on the official application blank in such form as may be adopted from time to time by the board of directors and when accompanied by an application fee in such amount as may be fixed from time to time by the board of directors.

SECTION 2. Form of Certificates. There shall be separate certification in psychiatry and in neurology and two certifications or a combined certification for those qualified in both fields. The certificates shall be in such form as is approved by the board of directors.

SECTION 3. Requirements for Applicants. Each applicant for a certificate must establish that—

(a) He is a physician duly licensed by law to practice medicine.

(b) He is of satisfactory ethical and professional standing.

(c) He is now a member of the American Medical Association, or a member of such medical societies as are recognized for purposes of certification by the Council on Medical Education and Hospitals of the American Medical Association.

(d) He has received adequate training in psychiatry or neurology, or both, as a specialty.

SECTION 4. No candidate is eligible for examination by the Board until he has completed at least five years of special training and experience in neurology or psychiatry for a single certificate, or at least six years of training and experience for certification in both neurology and psychiatry.

CLASSES OF APPLICANTS AND FEES

Applicants may request certification in psychiatry, or in neurology, or in both psychiatry and neurology.

Limitation of practice to the specialty of psychiatry and/or neurology need not be complete provided a candidate both by his previous training, experience and standing, and by examination, can prove his competency to practice that specialty.

However, in case a physician has already been certified by one of the other boards as a specialist in another field, he will not be considered for certification in psychiatry and/or neurology.

Class I

Physicians who graduated from medical school in 1919 or before and who have carried on specialized practice in neurology and/or psychiatry for at least fifteen years are to be

* A maximum of six months of this time may be spent in full time contagious work in a recognized hospital.

† The three volumes on Growth and Development of the White House Conference contain this material. Century Company, publishers.

considered on their professional record and passed, if satisfactory to the Board, or further evidence of qualification or examination may be required.

A candidate in Class I who has received certification in either psychiatry or neurology may apply within three years for certification in the other field without additional fee. After three years such application shall be considered as a new application with corresponding fees.

When certification in Class I has been refused, the candidate may file application for reconsideration within three years without additional fee. After three years such application for reconsideration shall be considered as a new application with corresponding fees.

Class II
Physicians who graduated from medical school up to and including 1929 and who have practiced the specialty of psychiatry and/or neurology for at least five years will be required to pass an examination in psychiatry or neurology, or both.

Class III
Physicians who graduated after 1929, up to and including 1934, will be required to pass an examination to satisfy the Board that they have adequate knowledge of all subjects specified in the by-laws for candidates graduating after 1934. Their previous training and experience must be acceptable to the Board.

Class IV
Candidates graduating from medical school after 1934 shall fulfil the preceding general requirements as given in Section 3 of Article VII and the following special requirements:

PROFESSIONAL EDUCATION

- (1) Graduation from a medical school approved by the Council on Medical Education and Hospitals of the American Medical Association.
- (2) Completion of a general internship of not less than one year in a hospital approved by the same Council.

SPECIAL TRAINING

(These requirements are to be placed in force as soon as practicable after Jan. 1, 1940. In the meantime a syllabus covering the knowledge required of the candidate has been prepared and is available to those who request it.)

Admission to the examination for certification in neurology or psychiatry requires a total experience of not less than five years. This period shall include the following:

1. A period of study, after the general internship, of not less than three full years in institutes, hospitals, clinics, dispensaries, laboratories, and other institutions recognized by the Council of the American Medical Association and approved by the American Board of Psychiatry and Neurology as competent to provide a satisfactory training in psychiatry and/or neurology.

(a) As subject matter,

Neuro-anatomy
Neurophysiology
Neuropathology
Clinical neurology

Psychobiology
Psychopathology
Neuro-röntgenology
Clinical psychiatry

and other basic medical sciences, which, in the opinion of this board, are necessary to the proper understanding and treatment of psychiatric and/or neurologic disorders.

2. An additional period of not less than two years of practice in psychiatry and/or neurology.

3. Candidates wishing to be admitted to the examinations for certification in both fields must have had a minimum of six years of experience in both fields.

PAYMENT OF FEES

The candidate on filing his application shall accompany it with an application fee of \$25. When notified by the Secretary that he is eligible for examination he shall send the examination fee of \$25 to the secretary at least two weeks before the date of the examination. The certification fee of \$25 is payable upon notification by the Board that certification has been awarded the candidate in Class I on his record. No fees will be returned.

The same examination is given whether a candidate applies for certification in psychiatry, or in neurology, or in both psychiatry and neurology. The Board requires some proficiency in neurology on the part of those it certifies in psychiatry and vice versa, but judges the candidate in accordance with the certificate he seeks.

Should a candidate receive certification in either psychiatry or neurology, he may apply within three years for partial examination for the certificate in the complementary subject, upon payment of a complementary examination fee of \$10. After three years, the second application shall be considered a new application, with corresponding \$25 fees.

EXAMINATIONS

Date and places of examination are set by the Board at its discretion and are announced in *The Journal of the American Medical Association*, in the *American Journal of Psychiatry*, in the *Journal of Nervous and Mental Disease*, and in the *Archives of Neurology and Psychiatry*.

The examinations are designed to test the ability of the candidates to meet the situations in which they might at any time be called upon as specialists to assume responsibility. They will be of such a type that no adequately trained individual will fail, yet they will be sufficiently searching so that the specialist-candidate is required to identify and to discuss the function of the more important anatomic structures in the brain and spinal cord, to discuss gross and microscopic pathologic specimens and to interpret roentgenograms dealing with neurologic disorders. He is examined orally on the subjects of psychobiology and psychopathology. These examinations in the preclinical subjects usually last about two hours. Each candidate examines two patients with neurologic disorders and two with psychiatric disorders, and discusses with the examiners the various problems involved. One hour, on the average, is allotted to each of these four clinical examinations. The manner of examining deductions therefrom constitute the most important part of the examination. Some acquaintance with the history of psychiatry and neurology, with the body of doctrine, and with the recent advances, is presupposed.

REEXAMINATIONS

A candidate who has failed in one examination is eligible to reexamination in the whole subject, within three years, on payment of a reexamination fee of \$10. A candidate who has failed in one examination and who does not apply for reexamination within three years or a person who has applied within that time but who has failed a second time will be considered a new applicant, with corresponding \$25 fees. The \$10 reexamination fee also applies to candidates conditioned in one or more subjects at any time within three years of the first examination, and is payable before each reexamination.

HANDLING OF APPLICATIONS

An application, in order to be considered at any meeting, must be in the hands of the secretary of the board not less than seventy days before the date of such meeting.

The secretary of the Board on receipt of an application shall forthwith make inquiries from those to whom the candidate refers and from such other persons as the secretary may deem desirable and shall verify the candidate's record from the biographical records of the American Medical Association, after which he shall forward the application to the committee on other information available and notify the secretary whether the application is accepted. The certification of a candidate in either psychiatry or neurology, or both, shall be approved by a majority of the members of the entire Board at any meeting held for such certification.

PLEDGE

Each candidate is required to sign the following pledge:

"I hereby make application to the American Board of Psychiatry and Neurology, Incorporated, for the issuance to me of a certificate of qualification as a specialist in (a) Psychiatry; (b) Neurology; (c) Psychiatry and Neurology (check the one desired) and for examination relative thereto, all in accordance with and subject to its rules and regulations. Upon the issuance of the certificate I agree to and do become bound by the by-laws of the American Board of Psychiatry and Neurology, Inc., insofar as applicable.

"I agree to disqualification from examination or from the issuance of a certificate of qualification or to forfeiture and redelivery of such certificate of qualification in the event that any of the rules governing such examination are violated by me or for any one of the reasons set forth in the by-laws. I agree to hold said American Board of Psychiatry and Neurology, Inc., its members, examiners, officers and agents, free from any damage or claim for damage or complaint by reason of any action they, or any of them, may take in connection with this application, such examination, the grade or grades given with respect to any examination, and/or the failure of said corporation to issue to me such certificate of qualification."

RULES AND REGULATIONS (ART. VII, SEC. 5, OF THE BY-LAWS)

The board of directors, from time to time, by resolution adopted by the affirmative vote of a majority then in office, may adopt, amend and repeal rules and regulations respecting requirements of applicants, the nature and extent of examinations and investigations and issuance of certificates.

REVOCATION OF CERTIFICATES (ART. VII, SEC. 6, OF THE BY-LAWS)

All certificates issued by the corporation shall be issued subject to the provisions of the certificate of incorporation and of the by-laws of the American Board of Psychiatry and Neurology, Inc. Each such certificate shall be subject to revocation in the event that:

(a) The issuance of such certificate or its receipt by the physician shall have been contrary to or in violation of any of the provisions of the corporation's certificate of incorporation or by-laws; or

(b) The physician so certified shall not have been eligible in fact to receive such certificate, irrespective of whether or not the facts constituting him so ineligible were known to any or all of the directors of the corporation or could have been ascertained by any or all of the directors of the corporation at the time of the issuance of such certificate; or

(c) The physician so certified shall have made any deliberate misstatement of fact in his application for such certificate or in any other statement or representation to the corporation, its directors, representatives or agents; or

(d) The physician so certified shall have been convicted by a court of competent jurisdiction of a felony or of any misdemeanor involving, in the opinion of the board of directors of the corporation, moral turpitude in connection with his practice of medicine; or

(e) The physician so certified shall have had his license to practice medicine revoked or shall have been disciplined or censured as a physician by any court or other body having proper jurisdiction and authority.

FORM OF CERTIFICATE

The secretary shall have prepared subject to the approval of the board members a form of certificate containing the following wording:

THE AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY, INC.

This is to certify that.....has satisfied the requirements of the board and is hereby certified as qualified to practice the specialty of Psychiatry and/or Neurology.

(Signed) President.....
Vice President.....
Secretary

Communications should be addressed to the secretary.

HISTORY AND AUTHORITY FOR ORGANIZATION

The medical profession has long felt that there should be a standard of minimal requirements for the practice of any specialty in medicine in order to protect the public, the profession in general, and the specialists themselves. Some of the states have attempted by statute to prescribe such requirements in certain branches. Unless a better method of regulation were found, the other states would be likely to enact similar laws. The result would be forty-eight different standards for each of the many medical specialties. Obviously, a more practicable solution would be for each special group to put its own house in order and place its mark of approval on those qualified to practice as specialists in that particular field. Accordingly, in 1932, five nation-wide radiologic organizations, the Section on Radiology of the American Medical Association, the American Roentgen Ray Society, the Radiological Society of North America, the American College of Radiology, and the American

Radium Society, each appointed a committee of three members to confer and investigate the feasibility of establishing a qualifying board. The following men were appointed by these five organizations: Drs. G. W. Holmes, J. W. Pierson, E. L. Jenkinson, W. E. Chamberlain, E. C. Ernst, W. F. Manges, L. R. Sante, L. C. Kinney, A. C. Christie, Albert Soiland, W. W. Wasson, Henry Schmitz, Lester Hollander, Rollin H. Stevens and B. R. Kirklin.

This combined committee met at Milwaukee in 1933, during the meeting of the American Medical Association, agreed unanimously that such a board should be established and so reported to the respective organizations. Each of the organizations approved the report, appointed three representatives, and empowered them to proceed to the formation of a national radiologic board. The members of the board thus chosen were: Drs. W. F. Manges, L. R. Sante and B. R. Kirklin, representing the American Roentgen Ray Society; Drs. A. C. Christie, E. C. Ernst and E. L. Jenkinson (succeeding Dr. Byron H. Jackson, originally appointed) representing the American College of Radiology; Drs. R. H. Stevens, Henry Schmitz and H. K. Pancoast, representing the American Radium Society; Drs. L. J. Menville, M. C. Sosman and Albert Soiland, representing the Radiological Society of North America, and Drs. L. C. Kinney, J. W. Pierson and G. W. Holmes, representing the Section on Radiology of the American Medical Association.

The board was incorporated, organized and held its first meeting in Washington, D. C., in May 1934; at that time the by-laws were adopted and provision was made by resolution for its proper function. The officers of the board elected at this meeting were:

Dr. H. K. Pancoast, President.
Dr. A. C. Christie, Vice President
Dr. B. R. Kirklin, Secretary-Treasurer.

This move put into action the determined effort on the part of these five national organizations to improve the standards of the practice of radiology. It expects to accomplish this by various activities, such as the investigation and encouragement of facilities for graduate extension study and active clinical assistantships for men desiring to specialize in radiology; it will endeavor by regular examinations to determine the competence of specialists in radiology who apply for the certificate.

During 1935 the American Board of Radiology was accepted for membership in the Advisory Board for Medical Specialties and was also approved by the Council on Medical Education and Hospitals of the American Medical Association. Hereafter the list of Diplomates of the Board will take the place of the Council's list of approved radiologists, and the latter list will be discontinued.

PURPOSES

First: To encourage the study and promote and regulate the practice of radiology.

Second: To elevate the standards and advance the cause of radiology by encouraging its study and improving its practice.

Third: To determine the competence of specialists in radiology; to arrange, control and conduct investigations and examinations; and to test the qualifications of voluntary candidates for certificates to be issued by the board.

Fourth: To serve the public, physicians, hospitals and medical schools by preparing lists of practitioners who shall have been certified by the board.

VALUE OF CERTIFICATE

The national radiologic organizations which have participated in the formation of the board and are sponsoring its activities, as well as other organizations, attach considerable importance to its certificate. It is expected that both the medical and the lay public, including hospital directors, will soon come to utilize the certificate from this board as a means of discriminating between those who are well grounded as specialists in radiology and those who are not.

To this end lists of those holding certificates from this board will be published and issued from time to time by the board. Similar lists will be published by the *American Journal of Roentgenology and Radium Therapy*, *Radiology*, and *The Journal of the American Medical Association*. The Directory of the American Medical Association will indicate by a numerical symbol in the biographic data of those whose names are eligible to appear on these lists that they are diplomates of this board.

For emphasis it is repeated that the board does not intend in any way to interfere with or limit the professional activities of any duly licensed physician, but it does aim toward standardized qualifications for those who claim to be specialists in radiology.

CERTIFICATES

A certificate will be issued to each candidate who meets the requirements of the board, to the effect that the holder of the certificate has had adequate training in radiology and has successfully fulfilled the requirements of the board.

A certificate granted by this board does not of itself confer, or purport to confer, any degree, or legal qualifications, privileges, or license to practice radiology. Certificates of the board shall be issued upon one of two forms:

1. A certificate to the effect that the applicant has been found qualified to practice radiology in all its branches.

2. A certificate to the effect that the applicant has been found qualified to practice radiology in one or more of the following special fields: (a) roentgenology; (b) diagnostic roentgenology; (c) therapeutic radiology.

DEFINITIONS

For the purposes of this board, the following definitions are adopted:

1. Radiology is that branch of medicine which deals with the diagnostic and therapeutic application of radiant energy including roentgen rays and radium.

2. Roentgenology is that branch of radiology which deals with diagnostic and therapeutic application of roentgen rays.

3. Diagnostic roentgenology is that branch of radiology which deals with the diagnostic application of roentgen rays.

4. Therapeutic radiology is that branch of radiology which deals with the therapeutic application of roentgen rays and radium.

GENERAL REQUIREMENTS

Each applicant for admission to the examination shall be required to present evidence that he has met the following standards:

(A) General Qualifications.*

(1) Satisfactory moral and ethical standing in the profession.

(2) A license to practice medicine.

(3) Membership in the American Medical Association, or, by courtesy, membership in such Canadian or other medical societies as are recognized for this purpose by the Council on Medical Education and Hospitals of the American Medical Association.

(4) That the applicant holds himself out to be a specialist in radiology or one of its branches as defined under definitions, and that he uses roentgen rays or roentgen rays and radium either personally or under his direct supervision in a substantial portion of his practice.

(B) Professional Education.*

(1) Graduation from a medical school of the United States or Canada, recognized by the Council on Medical Education and Hospitals of the American Medical Association.

(2) Completion of an internship of not less than one year in a hospital approved by the same council.

(3) Three years' training in radiology or sufficient experience in lieu thereof.

(C) Special Training.* (To be effective Jan. 1, 1942.)

(1) A period of study after the internship of not less than three calendar years in an institution or radiologic department recognized by the same council and the board as competent to provide a satisfactory training in the field of radiology.

(2) This period of specialized preparation shall include:

(a) Graduate training in pathologic anatomy, radiophysics, and radiobiology.

(b) An active experience of not less than twenty-four months in a radiologic department recognized by the board and the council as capable of providing satisfactory training.

(c) Examination in the basic sciences of radiology as well as in the clinical aspects thereof.

APPLICATIONS

The board desires to appraise the candidate's educational opportunities (premedical, medical and radiologic), the ability of his instructors, his hospital and teaching positions, his original investigations, his contributions to radiologic literature, his membership in medical societies, and his local and general reputation.

For this purpose, application must be made on a special blank which may be obtained from the secretary. No application will be considered unless made on the regular application blank. This application shall be forwarded with the required data, two unmounted photographs, and the fee of \$35, at least two months before the date of the examination.

* NOTE: In case of an applicant whose training has been received outside of the United States and Canada, the credentials must be satisfactory to the Advisory Board for Medical Specialties.

FEE

A fee of \$35 must accompany each application blank. This fee will not be returned and no application will be considered until the fee is received. This fee has been carefully computed and is used entirely for administrative purposes. Members of the board and special examiners do not receive any compensation except for actual expenses connected with holding the examinations. As the number of candidates decreases, it may become necessary to raise the fee.

Checks should be made payable to the American Board of Radiology.

EXAMINATIONS

Each year the board will hold an examination in conjunction with the annual meeting of the American Medical Association, and, when sufficient applications are on file, a second examination will be held in conjunction with the annual meeting of the American Roentgen Ray Society and/or the Radiological Society of North America.

For the present, examinations consist of practical and oral examinations, although written examinations may be added later. The examinations are designed to test the candidate's fitness to practice radiology or one of its branches as a specialty. The board will endeavor to adapt this examination to the candidate's experience and years of practice. It will try especially to ascertain the breadth of his clinical experience, his knowledge of the basic sciences of radiology, and likewise his knowledge of the recent literature on radiology, and his general qualifications as a specialist in this branch of medicine.

The examination consists of tests in film interpretation and an oral examination in pathology, physiology, radiophysics and radiobiology, as well as the clinical applications of roentgen rays and radium. The applicant is also examined in "professional adaptability," in an attempt to ascertain his attitude toward his fellow practitioners and his patients.

Whenever an applicant fails to pass the examination, the board, if requested, will make suggestions as to suitable courses of instruction for the purpose of overcoming his deficiencies.

REEXAMINATIONS

If the candidate fails in an examination he will be admitted to a second examination after one year has elapsed but not more than three years. He must give sixty days' notice of his intention to appear for reexamination and pay an additional fee of \$15. If a candidate who has failed does not appear for reexamination before the expiration of three years, he will be required to make a new application and pay an additional fee of \$35.

A candidate having failed twice must file a new application and pay an additional fee of \$35.

FINAL ACTION OF THE BOARD

The final action of the board is based on the applicant's professional record, training, and attainments in the field of radiology, as well as on the results of his examination. Any radiologist who is practicing radiology honorably and efficiently should have no difficulty in obtaining a certificate. This board has been organized, not to prevent qualified radiologists from obtaining certificates, but to assist them in becoming recognized in their communities as men competent to practice in the special field of radiology.

REVOCATION OF CERTIFICATES

Certificates issued by this board are subject to the provisions of the Articles of Incorporation and the By-Laws. According to Article IX, Section 4, of the By-Laws "Any certificate issued by the Board of Trustees shall be subject to revocation in the event that:

(a) The issuance of such certificate or its receipt by the physician so certified shall have been contrary to or in violation of any provision of the Certificate of Incorporation of this the American Board of Radiology or of these by-laws; or

(b) The physician or party so certified shall not have been eligible in fact to receive such certificate; or

(c) The physician or party so certified shall have made any misstatement of fact in his application or in any other communication to the board or its representatives; or

(d) The physician or party so certified shall have been convicted by a court of competent jurisdiction of a felony or of any misdemeanor involving, in the opinion of the Board of Trustees, moral turpitude; or

(e) If the physician or party so certified shall have had his license to practice medicine revoked or shall have been expelled

from one of the societies or organizations which is represented by this corporation through eligibility of such society or organization to nominate and appoint members of this corporation."

Communications should be addressed to the secretary.

PHILEMON E. TRUESDALE, Fall River, Mass.

HISTORY

The organization of the American Board of Surgery was completed on Jan. 9, 1937. A plan for this organization had been carefully studied by a general committee representative of certain general and sectional surgical societies called together through the initiative of the American Surgical Association. As a result of the deliberations of this general committee a tentative plan of organization was adopted. This plan was reported to the cooperating surgical societies and was approved with the understanding that the board, when organized, would have the power to change or modify the proposed plan as it saw fit. This board has been created in accordance with the action of the Advisory Board for Medical Specialties as approved by the Council on Medical Education of the A. M. A., which has named twelve specialty fields as being suitable to be represented by such boards. These boards have the two-fold purpose of certifying those found to be qualified after meeting reasonable requirements, and of improving existing opportunities for the training of specialists within the field concerned. This is to be done for the protection of the public and the good of the specialty.

PERSONNEL

*The cooperating surgical societies selected jointly to form the board appointed their representatives as follows:

The American Surgical Association.....	3
The Surgical Section of the A. M. A.....	3
The American College of Surgeons.....	3
The Southern Surgical Association.....	1
The Western Surgical Association.....	1
The Pacific Coast Surgical Association.....	1
The New England Surgical Society.....	1
	—
	13

The term of membership is for six years. Each cooperating association has the appointing power of its representatives subject to the approval of the board.

PURPOSES

(a) To conduct examinations of satisfactory candidates who seek qualification by the Board.

(b) To issue certificates of qualifications to all those meeting the Board's requirements.

(c) To improve the opportunities for the training of the surgeon.

REQUIREMENTS

(A) GENERAL QUALIFICATIONS

1. Moral and ethical standing in the profession satisfactory to the Board.

The Board, believing that the practice of "fee splitting" is pernicious, leading as it does to a traffic in human life, will reserve the right to inquire particularly into any candidate's practice in regard to this question.

*The first three of these associations being national in scope, were allotted three representatives each, the remaining associations, one.

2. Membership in the American Medical Association or, by courtesy, membership in such Canadian or other medical societies as are recognized for this purpose by the Council on Medical Education and Hospitals of the A. M. A. Except as here provided, membership in other societies shall not be required.

3. Those who have limited their activities to the practice of surgery.

4. In exceptional instances the Board may, in its discretion, accept for examination candidates who have met all preliminary requirements and have been in practice from six to sixteen years but whose formal training does not comply with the full requirements to be exacted in the future.

The Board recognizes two groups of candidates who may be eligible for certification.

(A) The Founders Group—those who have already amply demonstrated their fitness as trained specialists in surgery. Candidates from this group on invitation by the Board may make application and upon approval by the Board will be accepted without examination as qualified. This group will be selected from the following:

1. Those who from the time of the Board's organization, January 9, 1937, hold the position of Professor or Associate Professor of Surgery in the approved medical schools of the United States or Canada.

2. Those who for fifteen years prior to the Board's organization have limited their practice to surgery and have met the general qualifications required.

3. Such members of the cooperating societies represented on the Board, in good standing January 9, 1937, who may be invited to membership in this group.

(B) Qualified by examinations—

In addition to the general qualifications the requirements for this group shall be as follows:

(B) PROFESSIONAL STANDING

1. Graduation from a medical school of the United States or Canada recognized by the Council on Medical Education and Hospitals of the A. M. A., or graduation from an approved foreign school.

2. Completion of an internship of not less than one year in a hospital approved by the same Council, or its equivalent in the opinion of the Board. This internship may be rotating or one devoted to a single branch of medicine as, for example, surgery, medicine, pathology, etc.

(C) SPECIAL TRAINING

After the completion of the year's internship there shall be a period of special training in surgery of not less than five years. During this period one's entire time must be devoted to surgical training supplemented by sufficient experience in the basic sciences to comply with the provisions of Paragraph 2. Such training may be taken in a recognized graduate school of medicine, or as resident in surgery in an acceptable hospital, or under a sponsorship accredited by the American Board of Surgery for such training. By the latter statement is meant that one may secure the necessary training as an assistant to an accredited surgeon, provided suitable facilities for the education of the candidate are offered. It is understood that the Board will accept a combination of training as outlined above—for example, one may take a graduate course in an acceptable graduate school for one year, a residency of two years, and an assistantship of two years.

This period of special training shall be of such character that the relation of the basic sciences of anatomy, physiology, pathology, bacteriology and biochemistry is emphasized. Knowledge of these sciences as applied to clinical surgery will be required in the examination.

Adequate operative experience in which the candidate has assumed the whole responsibility will be required.

The above requirements, especially those referring to surgical training, are subject to change from time to time as the existing opportunities for training in this field of specialization may be broadened.

EXAMINATIONS

The qualifying examination will be divided into Part I (written) and Part II (clinical, bedside and laboratory). In both of these parts a knowledge of the practical application of the sciences fundamental to surgery will be required as previously stated.

PART I

This may be given simultaneously in as many centers as the Board may determine suitable for the purpose. A candidate, to be eligible for Part I, must meet all requirements for Group B.

candidates. A card of admission to this part of the examination will be forwarded to the candidate from the Secretary's office, certifying that these requirements have been met, as well as due notice as to the time and place of examination.

The examination in Part I shall cover a one day period. There shall be two sessions of three hours each. This written examination shall concern itself primarily with general surgical problems and in addition the application of the basic sciences of surgery to these problems.

PART II

In order to be eligible for Part II a candidate must have successfully passed Part I, in addition to having met the necessary preliminary requirements and having presented definite evidence of an adequate training in operative surgery satisfactory to the Board.

This Part of the examination shall be oral and practical and cover a two day period, the schedule being arranged somewhat as follows:

FIRST DAY

8-9 A. M.—Registration.

9 A. M.-1 P. M.—Clinical Surgery (diagnosis and management).

2-5 P. M.—Surgical Pathology, clinical application of Physiology, Biochemistry and Bacteriology to Surgery, x-ray plate interpretation, Anesthesia.

SECOND DAY

9 A. M.-1 P. M.—Operative Surgery.

2-5 P. M.—Special Examinations (reexaminations when necessary).

It is probable that for the present this Part of the examination can be held in one center or at the most, two. Later, however, as the demand grows, it will be necessary, in all probability, for the Board to establish definite subsidiary board centers where this Part may be held. At that time it will be necessary that the Board appoint subsidiary boards in these centers, consisting of those already qualified as in Group A, to conduct this examination.

GRADES

A candidate must receive a passing average for each Part to be entitled to the Board's certificate. No candidate shall pass a Part who does not receive a grade of 60% or over in each subject of such a Part. An average grade of 75% shall be considered as passing in each Part.

A candidate who fails in his examination in Part I shall have his papers reviewed by the Examination Committee.

REEXAMINATIONS

Candidates may be reexamined as often as they desire provided one year shall elapse between examinations, except that the Board may, for good and sufficient reason, deny a candidate the privilege of reexamination.

Candidates shall be required to pay the same fees for Parts I and II at each reexamination in these Parts.

FEES

The fee for Group A, Founders Group, shall be \$25.

The fee for Group B shall be \$75, payable as follows: \$5 registration fee, which shall be returned if the candidate is not accepted for examination; \$20 for Part I; and \$50 for Part II.

This Board is a non-profit organization. All fees will be used, after a reasonable amount is set aside for necessary expenses in maintaining its office, conducting examinations, etc., to aid in improving existing opportunities for the training of the surgeon.

CERTIFICATE

A certificate attesting to a candidate's qualification in surgery after meeting the requirements will be issued by the Board, having been signed by its officers.

REVOCATION OF CERTIFICATE

Any certificate issued by the Board shall be subject to revocation by the Board at any time in case it shall determine in its sole judgment that a candidate who has received a certificate either was not properly qualified to receive it or has become disqualified since its receipt.

Proper forms for making application, and, other information, will be furnished by the secretary.

AMERICAN BOARD OF UROLOGY, Inc.

HERMAN L. KRETSCHMER, President, Chicago.

CLARENCE G. BANDLER, Vice President, New York.

GILBERT J. THOMAS, Secretary-Treasurer, 1009 Nicollet Avenue, Minneapolis.

NATHANIEL P. RATHBUN, Brooklyn.

GEORGE GILBERT SMITH, Boston.

WILLIAM F. BRAASCH, Rochester, Minn.

HENRY G. BUGBEE, New York.

ALFRED I. FOLSOM, Dallas.

T. LEON HOWARD, Denver.

ORGANIZATION

At the annual meeting of the American Association of Genito-Urinary Surgeons held at Niagara Falls, Ont., Canada, May 26-28, 1932, Dr. William F. Braasch called attention to the various qualification boards which had been established, or were in the process of being established, for the certification of specialists. He suggested that a committee should be appointed from this organization to investigate the advisability of establishing a similar board for the specialty of urology. A committee consisting of Dr. Braasch as Chairman, Dr. Henry G. Bugbee, and Dr. Hugh H. Young was appointed. This committee reported to the society in 1933, was reappointed to continue its efforts, and was given the power to act.

At the meeting of the American Urological Association in 1933, Dr. George R. Livermore, in his presidential address, suggested that all candidates for specialization in urology should have some definite preparation, and should be required to take a thorough examination before being recognized as specialists in urology. Dr. Livermore appointed Dr. Joseph F. McCarthy, chairman; Dr. George Gilbert Smith, and Dr. Herman L. Kretschmer as a committee to study this suggestion.

At the annual meeting of the American Medical Association in Milwaukee, June 12-16, 1933, a committee consisting of Dr. Montague L. Boyd, chairman; Dr. A. I. Folsom and Dr. Frank Hinman was appointed to cooperate with similar committees from the American Association of Genito-Urinary Surgeons and the American Urological Association in the establishment of the American Board of Urology.

The first combined meeting of the committees from these three organizations was held on Oct. 11, 1933, in Chicago. Dr. Herman L. Kretschmer was made president; Dr. Joseph F. McCarthy, vice president; and Dr. William F. Braasch, secretary. These men were elected to serve as temporary officers. A permanent organization could not be effected, however, because the committee from the American Urological Association had not been given the power to act.

The second meeting of these committees was held in New York City, Feb. 2, 1934. Dr. Nathaniel P. Rathbun, president of the American Urological Association, was present at this meeting.

At the annual meeting of the American Urological Association held in Atlantic City, N. J., May 22-24, 1934, the committee reported the activities of the temporary "Board of Urology." This report, which contained suggestions for the guidance of future committees from this association, was accepted, and a new committee was elected by the association, and was given the power to act.

The permanent "American Board of Urology, Inc.," was organized at Chicago, Sept. 24, 1934. The committee members present from the American Association of Genito-Urinary Surgeons were: Dr. William F. Braasch, Dr. Henry G. Bugbee, and Dr. Gilbert J. Thomas; those from the American Urological Association were: Dr. Nathaniel P. Rathbun, Dr. Herman L. Kretschmer, and Dr. George Gilbert Smith; those from the Section on Urology of the American Medical Association were: Dr. A. I. Folsom, Dr. T. Leon Howard, and Dr. Clarence G. Bandler.

The officers of the board elected at this meeting were: Dr. Herman L. Kretschmer, president; Dr. Clarence G. Bandler, vice president; Dr. Gilbert J. Thomas, secretary-treasurer.

The board was incorporated May 6, 1935, and held its first legal meeting May 10, 1935.

PURPOSES

The first objective of the American Board of Urology, Inc., is to render better service to the public by insuring the competence of any physician or surgeon who is specializing, or who wishes to specialize, in the field of urology. It will elevate the standards and advance the cause of urology. It will investigate the curricula of medical schools, and will encourage adequate facilities for graduate instruction in urology.

FUNCTIONS

(a) The board will arrange to control and conduct examinations testing the qualifications of volunteer candidates.

(b) The board will grant and issue certificates or other evidence of special knowledge in the field of urology to voluntary applicants or to candidates for certification.

(c) The board will endeavor to serve the public, hospitals, medical schools, medical societies and practitioners of medicine and surgery by preparing lists of urologists whom it has certified.

LIMITATIONS OF FUNCTIONS

The conferring of degrees, "Doctor of Medicine" or "Bachelor of Medicine" remains with the universities, where it belongs, and this board makes no attempt to control the practice of urology by license, or legal regulations. This board does not intend in any way to interfere with or limit the professional activities of any duly licensed physician.

REASON FOR APPLYING FOR A CERTIFICATE; ITS VALUE

The American Urological Association, the American Association of Genito-Urinary Surgeons, and the Section on Urology of the American Medical Association are interested in furthering the cause of urology and have participated in the formation of this board. They are sponsoring its activities. The various national medical societies, the public, hospital directors and others, will utilize the certification from this board as a means of discriminating between those well grounded as specialists in urology, and those who are not.

Lists of individuals who have certificates from this board, and who are engaged in the practice of urology may be published in the Directory of the American Medical Association and will be published in a booklet issued from time to time by the American Board of Urology, Inc. The directory of the American Medical Association may indicate, by symbols in the biographical data, those whose names are eligible to appear on the list of diplomates of this board.

Application for this certificate is purely voluntary. There is only one type of certificate. No indication is given as to whether or not the candidate received his certificate with or without examination. All certificates are identical.

The Advisory Board for Medical Specialties working in conjunction with, and reporting to, the Council on Medical Education and Hospitals of the American Medical Association, has set certain standards of preparation for specialization which the American Board of Urology, Inc., wishes to adopt. The advisory board has drawn from the experience of all the present functioning boards, and has been of inestimable assistance in the formulation of the Constitution and By-Laws for the Board of Urology. Other organizations which now successfully operate boards of certification are:

The American Board of Ophthalmology, the American Board of Otolaryngology, the American Board of Obstetrics and Gynecology, the American Board of Dermatology and Syphilology, the American Board of Pediatrics, the American Board of Psychiatry and Neurology, the American Board of Radiology, the American Board of Orthopedic Surgery, the American Board of Internal Medicine, the American Board of Pathology and the American Board of Surgery. Among the organizations cooperating with the Advisory Board for Medical Specialties are: the Association of American Medical Colleges, the American Hospital Association, the Federation of State Medical Boards of the U. S. A., and the National Board of Medical Examiners.

APPLICATION BLANK: REQUIREMENTS FOR ALL APPLICANTS

Application for certification must be made on a special blank. This will be provided by the secretary and must be returned to him accompanied by other required data and credentials, and by the examination fee.

Requirements for Applicants. (Article VIII, Section 2, of the By-Laws of the American Board of Urology, Inc.)

Each applicant, before he shall become eligible to take the examination for certification in urology, must:

A. Have graduated from a medical school of the United States or Canada recognized by the Council on Medical Education and Hospitals of the American Medical Association, and must have completed an internship of not less than one year in a hospital approved by the same council. (The former requirement is not applicable to a candidate who graduated from an institution now extinct, or whose graduation occurred

before the American Medical Association had prepared a list of accredited medical schools.) All graduates of foreign medical schools must obtain a license in the state in which they propose to practice medicine and the certificate of the National Board of Medical Examiners before making application for certification.

B. Establish in a manner satisfactory to this board that he is a physician duly licensed by law to practice medicine, that he is of high ethical and professional standing and that he has received adequate special training in urology.

The Board is attempting to increase and to standardize the facilities for urological training in teaching institutions, so that the expression "special training in Urology" may be interpreted to include:

1. A period of study, after the internship, of not less than three years in clinics, dispensaries, hospitals or laboratories recognized by the Council on Medical Education and Hospitals of the American Medical Association as competent to provide a satisfactory training in the special field of Urology.

This period of specialized preparation should include:

(a) graduate training in anatomy, physiology, pathology, and the other basic medical sciences which are necessary to the proper understanding of the disorders and treatment involved in the specialty of Urology.

(b) an active experience of not less than eighteen months in hospital clinics, dispensaries and diagnostic laboratories recognized by the Council on Medical Education and Hospitals of the American Medical Association as competent in the diagnosis and treatment of urologic conditions.

(c) examinations in the medical sciences basic to the specialty of Urology, as well as in the clinical, laboratory and public health aspects.

2. An additional period of not less than two years in the private practice of urology in the city from which he makes application.

These special requirements conform with the suggestions made by the Council on Medical Education and Hospitals of the American Medical Association.

C. Make application to the American Board of Urology, Inc., whose duty it shall be to investigate the applicant's credentials and make a survey of his character;

D. Assure the board that he is engaged in the practice of urology and that he intends to continue to be so engaged;

E. Membership in the American Medical Association, or comparable national medical society is recommended.

FEE

The examination fee will be \$50, which is the total expense to the candidate. If a candidate fails in his examination, he will be permitted a second examination after one year, or within three years, without additional fee, but he must give sixty days' notice of his intention to appear for reexamination. After an applicant has failed twice, he must file a new application blank accompanied by a second fee. If an applicant is lacking in any of the requirements as stated above, he will be considered ineligible for examination and classification and his fee will be returned. In no other instance, however, will a refund of the examination fee be possible. The amount of the examination fee has been carefully computed and is based on the experience of other boards.

REQUIREMENTS FOR CERTIFICATION

According to the By-laws of the American Board of Urology, Inc., applications received from applicants for certification, or other recognition, shall be examined by the Credentials Committee and reviewed by the board. When additional data are required to complete the application, these will be requested by the secretary's office.

The requirements for certification include: personal appearance before the board; preparation of fifty case reports of major urological cases under the candidate's own supervision, which must contain all items essential for diagnosis, therapy, prognosis, results of treatment, etc.; oral and clinical examinations; written examinations.

In specific instances, the board may waive any part of these requirements, with the exception of the item of personal appearance.

Each candidate will receive a notice of the time and place of the examinations, and an appointment for his personal appearance before the board.

EXAMINATIONS, WHERE HELD, AND REPORTS OF CASE HISTORIES

The board will attempt to hold one or more examinations per year. These will be held in association with the annual meetings of the American Urological Association or the American Medical Association, when this is practicable, or at other times and places that the board may select.

MEDICAL EDUCATION

821

1. The written examinations are designed to test the candidate's preparation in and his knowledge of the field of urology. These examinations will not be given at the time of the oral and clinical examinations, or board sessions, but will be held at stated intervals simultaneously in different parts of the country at dates and at places convenient for candidates; adequate time will be given for correction of papers before the oral and clinical examinations are held. Written examination papers will be reviewed by examiners who reside in districts remote from those in which the candidates reside.

2. The oral and clinical examinations will consist of discussions of common urologic conditions, with appropriate pathologic specimens and histologic sections. The subjects forming the basis of the oral examinations are anatomy, embryology, physiology, pathology, urography, diseases of the genital organs, including the prostate, diseases of the urinary bladder, and diseases of the ureters and kidneys. The oral examination may deal directly with the reports of case histories which the candidate has submitted. This examination will ascertain the candidate's familiarity with recent urologic literature, the breadth of his clinical experience, and his general qualifications as a specialist in urology. The applicant also will be examined in "professional adaptability" in an attempt to ascertain his attitude toward his fellow practitioners and his patients.

3. The fifty reports of major urological cases under the candidates' own supervision should be consecutive. Those prepared by candidates who are subject to the oral examination, only, must be submitted to the secretary of the board at least sixty days before the time set for the oral examination. Candidates who are subject to the written examination must submit their fifty reports of case histories at least sixty days before the time set for the oral examination, or at the time of the written examination.

Case reports may be abstracted, but sufficient data should appear in these so the examiner will know that a complete history was taken and that a thorough examination was made. The diagnosis made and the treatment prescribed must be justified by the facts that are elicited from the patient's history and during a complete examination. Case reports that are copied verbatim from a hospital record are not desired. They must be identified by the name of the hospital and the case admission numbers, with the pertinent dates. The reports must be typewritten and in duplicate, but need not be on any special forms. If the reports are prepared by record clerks, interns, or fellows, they should be reviewed by the candidate and careful attention given to the spelling and the correct use of medical terms.

A candidate must assume personal responsibility for his case reports. He should review them carefully before they are submitted to the secretary's office. A candidate must remember that these case reports are documentary evidence of his method of practice, and that the material in them and the manner in which it is presented reflect this.

Although the board requires that all the essential points of the history and examination be given, as well as a complete description of the surgical procedure, emphasis should be placed on the following items: preoperative diagnosis; clinical and pathological diagnosis; summary of postoperative course with special reference to morbidity; clinical findings at time of discharge from the hospital and subsequent "follow-up" reports. A final short paragraph must be prepared for each case by the candidate. These data must include the candidate's interpretation of the history in terms of pathology; the basis for the diagnosis; the facts that determined the treatment prescribed, whether surgical or otherwise; the course of treatment to be pursued following discharge from the hospital or clinic; a critical discussion of the knowledge gained from the proper handling of the case, or from the errors made (if any) in the diagnosis and method of treatment.

Complete separate index lists of the case history reports submitted must accompany the records. If the reports are obtained from more than one hospital they must be consecutive, as mentioned before, and a separate complete list of each group of reports should be provided. These lists must state the operator's name at the head of each page, the name of the patient, the hospital and admission number, and the date of operation. The lists will be filed in the secretary's office for verification purposes. Case reports will be reviewed by examiners living in localities other than those where the candidates practice.

FINAL ACTION

Final action is based on the applicant's training, his professional record, his attainments in the field of urology, and the results of the examinations. Any well trained urologist will have no difficulty in obtaining the board's certification. This board is organized not to prevent qualified urologists from obtaining certificates, but to assist them in becoming recognized in their communities as men competent to practice in the special field of urology. The activities described in Articles IX and X of this pamphlet proceed from the certificate of incorporation in which is stated the nature of the business, objects, and purposes proposed to be transacted and carried out by this corporation.

REVOCATION OF CERTIFICATE

Certificates issued by this board are subject to the provisions of the Articles of Incorporation and the By-laws. According to Article IX, Section 4, of the By-laws, "each certificate may be revoked in the event that:

- (a) The issuance of such certificate or its receipt by the physician so certified shall have been contrary to; or in violation of, any provision of the Certificate of Incorporation of this, the American Board of Urology, Inc., or of the By-laws; or
- (b) The physician or party certified shall not have been eligible to receive such certificate, irrespective of whether or not the facts constituting him so ineligible were known to, or could have been ascertained by, the directors of the board at the time of the issuance of such certificate; or
- (c) The physician or party so certified shall have made any misstatement of fact in his application for such certificate or in any other statement or representation to the board or its representatives; or
- (d) The physician so certified, at any time while continuing to practice, shall cease to practice urology; or
- (e) The physician so certified shall at any time have neglected to maintain the degree of competency in the practice of the specialty of urology as set up by the board, and shall refuse to submit to reexamination by the board.

The Board of Trustees of this Corporation shall have the sole power, jurisdiction and right, to determine and decide whether or not the evidence or information before it is sufficient to constitute one of the grounds for revocation of any certificate issued by this corporation, and the decision of such Board of Trustees in the premises shall be final." Communications should be addressed to the secretary-treasurer.

ADVISORY BOARD FOR MEDICAL SPECIALTIES

Organized 1933-1934 to coordinate graduate education and certification of medical specialists in the United States and Canada.

This Board reports directly to its member groups, and functions in close cooperation with the Council on Medical Education and Hospitals of the American Medical Association and the Advisory Council on Medical Education. The work of this Board has been aided by grants from the Josiah Macy Jr. Foundation of New York, but the Board is now supported by its component groups.

The Advisory Board for Medical Specialties has prepared this booklet for the purpose of furnishing general information regarding its activities in connection with graduate medical education and the certification of medical specialists in the United States and Canada. It was designed also to give detailed information concerning the procedures to be followed by examining Boards in the various specialties in order to obtain membership in this Advisory Board and official recognition by the Council on Medical Education and Hospitals of the American Medical Association. This information was based in large part on the experience of previously formed Boards during the past twenty-three years.

Examining Boards have now been organized, approved, and are actively functioning in the twelve specialties originally recognized as suitable fields for the certification of specialists. Two of the more limited specialties, namely, anesthesiology and plastic surgery have examining boards as affiliates of the American Board of Surgery.

The Committee on Standards and Examinations of the Advisory Board and the Council on Medical Education and Hospitals of the American Medical Association express themselves as opposed to the organization of examining boards in

any special field having less than one hundred in the United States engaged in the special practice in question.

ORGANIZATION

Several American Boards had been functioning actively and successfully for a number of years prior to the organization of the Advisory Board for Medical Specialties. Their purposes were, primarily, to establish minimum standards of graduate educational and training requirements for physicians representing themselves to the public as being specialists, with certification by the boards of candidates after they had been able successfully to pass the boards' examinations. Secondly, these boards hoped to improve the general standards of graduate medical education and facilities for special training. This aim is being steadily and rapidly accomplished.

Credit for the improvement in undergraduate medical education, so noticeable in this country during the past twenty-five years, is due to the efforts of universities, educational foundations, medical schools, medical societies, and to public support along these lines. The same is true of the present transition in graduate education in the specialties, sharply stimulated by the establishment and activities of these certifying boards.

The American Board of Ophthalmology was the first special certifying board to be created in 1916; the American Board of Otolaryngology, established in 1924, was followed by the American Board of Obstetrics and Gynecology in 1930, and the American Board of Dermatology and Syphilology in 1932.

During part of this period of time plans for the organization of similar boards in other specialties were being actively projected, all of these groups being desirous of availing themselves of the experiences of the already existing boards.

It was soon recognized that some formal and official plan of organization must be established. It was clearly essential that an examining board must have the official sanction of the National societies in its given specialty as well as that of its section of the American Medical Association, but there was, at that time, nothing to prevent unofficial groups from organizing examining Boards and using the title American Board.

Consequently, in order to avoid duplication of effort as well as to coordinate the work of the several boards and other interested groups into a concise and homogeneous plan for betterment, it was deemed advisable to create an Advisory Board which should give consideration to those problems common to all, and which should be representative of each organization concerned.

During the years 1933 and 1934 this Advisory Board was organized and began actively to function. Simultaneously at the Milwaukee session of the American Medical Association in 1933, a resolution was adopted authorizing the Council on Medical Education and Hospitals: (1) to formulate standards of administration based in general upon those of the American Boards of Ophthalmology, of Otolaryngology, of Obstetrics and Gynecology, and of Dermatology and Syphilology and, (2) to recognize officially new boards meeting these standards, this recognition to be based upon previous approval and recommendation to the Council by the Advisory Board.

A constitution and by-laws for the Advisory Board was adopted at a meeting in Chicago on February 11, 1934. The original member organizations of the Advisory Board for Medical Specialties were: the Association of American Medical Colleges; the American Hospital Association; the Federation of State Medical Boards of the U. S. A.; the National Board of Medical Examiners; the American Board of Ophthalmology; the American Board of Otolaryngology; the American Board of Obstetrics and Gynecology, and the American Board of Dermatology and Syphilology. Two representatives were appointed from each of these organizations to serve on the Advisory Board. Since that time the American Boards of Pediatrics, of Psychiatry and Neurology, of Radiology, of Orthopaedic Surgery, of Urology, of Pathology, of Internal Medicine, and of Surgery have been properly organized, approved, and elected to membership in the Advisory Board and recommended to the Council on Medical Education and Hospitals of the American Medical Association for official recognition. The American Board of Surgery now has two affiliate Boards (Anesthesiology and Plastic Surgery) functioning under its general direction and also represented in the Advisory Board.

PURPOSE

Article II of the Constitution states that, "This Board shall act in an advisory capacity to such organizations as may seek

its advice concerning the coordination of the education and certification of medical specialists." Specifically, this represents an official effort to advance the standards and improve the methods of graduate education and training in the medical specialties, with certification of men thus educated and trained who qualify as specialists in the various branches. The common interest of the member organizations in these purposes is obvious. It is equally apparent that some fixed definition of specialties needed to be established, preferably on a graduate educational basis, that minimum standards of organization and conduct for new examining boards should be fixed, and that some official method of recognition be developed.

There is no desire on the part of these boards to interfere with any practitioners of medicine in any of their regular or legitimate activities. Their fundamental purpose is to ensure to the public, both lay and medical, and for its protection, that physicians claiming to be specialists with presumably special proficiency in one or another branch of medicine actually possess the qualifications they claim. This presupposes special training and demonstrable capability along certain lines of work. Suitable evidence of this is the ability of an individual to satisfy an examining Board about his training and then to pass the examination for certification.

The function of each member organization and the relationship of interests will be apparent from a review of the names of these Committees and Boards.

Preparations for providing medical school and hospital facilities for the required graduate training are going forward actively; surveys of existing facilities for assistant residencies and residencies are being made at the present time in the several specialties; previous activities in the various States respecting the issuance of licenses to specialists are being discussed with a view to their being coordinated with the present activities of the several specialty boards.

Active plans are under way for the publication of a Directory of Medical Specialists to include the names and biographic data of all men certified by the several specialty Boards, as well as information regarding the organization and functions. The first edition of the Directory will appear late in 1939 and will contain the names and brief biographic records, including hospital and teaching appointments of more than 16,000 diplomates or certified specialists.

The Council on Medical Education and Hospitals of the American Medical Association has agreed, under the authority vested in it by the resolution passed at the Milwaukee meeting (1933) and referred to above, that applications of special examining boards for official approval are to be referred to the Council through the Advisory Board for Medical Specialists, recommendation by the Advisory Board for such approval to be based upon the standards mutually adopted. The understanding exists that the Council cannot be bound by recommendations of the Advisory Board but will consult the Advisory Board for Medical Specialists before acting upon any application so long as mutually adopted standards are in force. In response to the generally recognized need for a clear formulation of the educational problems and principles involved in graduate and postgraduate medical training, the Advisory Board at its meeting in June 1937 voted to create a Commission on Graduate Medical Education to study the various aspects of the whole problem. This Commission includes representatives of the profession, the specialties, the universities, the hospitals, and the licensing bodies. The results of the study contemplated should be of real assistance to the various specialty boards, hospitals, medical schools, and regulatory bodies dealing with this phase of American medicine.

MEMBERSHIP

The Advisory Board is composed of two representatives from each of the approved examining Boards in the medical specialties and such other national organizations as are interested in education, examination, and certification of medical specialists and duly elected to this body.

The Constitution provides that, "To be eligible for representation in this Board an examining board in a specialty must be composed of members elected from or appointed by societies recognized by this Board as a national society in that specialty together with representation from the related section of the American Medical Association." Upon being accepted by the Advisory Board the Board in question is recommended to the Council on Medical Education and Hospitals of the American Medical Association as qualified for recognition. Member-

ship in the Advisory Board provides for the inclusion of the name of the organization in all lists and directories published by the Advisory Board for Medical Specialties and provides also for publication of the names of specialists certified by each individual examining Board. Meetings of the Advisory Board for Medical Specialties are held annually as required. Traveling and other expenses of representatives in attendance are borne by member organizations.

ESSENTIALS FOR APPROVED SPECIAL EXAMINING BOARDS (Adopted by the Advisory Board for Medical Specialties, June 10, 1934)

I. ORGANIZATION

1. A special examining board to be approved by the Advisory Board for Medical Specialties should represent a recognized and distinct specialty of medicine. (It is agreed between the Council and the Advisory Board that no board shall be organized in a special field having less than one hundred members engaged in special practice in the United States.)

2. It should be composed of representatives of the national organizations in that specialty including the related section of the American Medical Association.

3. It should be incorporated.

4. A special board should:

- Determine whether candidates have received adequate preparation.
- Provide a comprehensive test of the ability and fitness of such candidates.
- Certify to the competence of those physicians who have satisfied its requirements.

II. DEFINITION OF SPECIAL FIELDS
The following branches of medicine at present are recognized as suitable fields for the certification of specialists:

- Internal Medicine
- Surgery
- Pediatrics
- Obstetrics and Gynecology
- Ophthalmology
- Otolaryngology
- Dermatology and Syphilology
- Psychiatry and Neurology
- Urology
- Orthopaedic Surgery
- Radiology
- Pathology

III. QUALIFICATION OF CANDIDATES

Each applicant for admission to the examination should be required to present evidence that he has met the following standards:

A. General Qualifications.

- Satisfactory moral and ethical standing in the profession as are recognized in such Canadian or other medical societies as are recognized for this purpose by the Council on Medical Education and Hospitals of the American Medical Association. Except as here provided, membership in other societies should not be required. (Exceptions to the foregoing may now be made at the discretion of any individual Board for good and sufficient reasons.)
- Professional Standing.

- Graduation from a medical school of the United States or Canada recognized by the Council on Medical Education and Hospitals of the American Medical Association.
- Completion of an internship, preferably of the general rotating type, of not less than one year in a hospital approved by the same Council.

C. Special Training.

- (To be effective as far as practical not later than January 1, 1942.)
- A period of study, after the internship, of not less than three years in clinics, dispensaries, hospitals or laboratories recognized by the same Council as competent to provide a satisfactory training in the special field of study.

2. This period of specialized preparation should include:

(a) Graduate training in anatomy, physiology, pathology, and the other basic medical sciences which are necessary to the proper understanding of the specialty in question.

(b) An active experience of not less than eighteen months in hospital clinics, dispensaries and diagnostic laboratories recognized by the Council as competent in the specialty.

(c) Examinations in the basic medical sciences of a specialty as well as in the clinical, laboratory and public health aspects.

3. An additional period of not less than two years of study and/or practice.

The foregoing report is practically identical with an outline of Essentials for Approved Specialty Boards adopted June 10, 1934, by the Council on Medical Education and Hospitals of the American Medical Association and ratified June 11, 1934, by the House of Delegates of the American Medical Association.

ORGANIZATION OF EXAMINING BOARDS

The foregoing essentials for approved special examining boards and their affiliate boards were followed in the organization of the existing boards.

Official sponsorship of the national societies, and the related section of the American Medical Association, in a specialty organizing an examining Board, has included the election or appointment of representatives from each of these national societies to serve on the Board as examiners and directors.

Each Board was or is incorporated. Each application for organization and approval included:

1. The name of the proposed Board.

2. A statement of its method of organization, the sponsoring societies, its list of officers, and the names and addresses of the elected or appointed members of the Board, including the societies which each represents.

3. A copy of the tentative constitution and by-laws.

4. A copy of its proposed articles of incorporation.

5. An outline of qualification requirements for applicants.

6. An outline of proposed methods of examination.

7. A copy of the application blank.

8. Any general information or statement of importance.

9. Approximate number of physicians practicing the specialty which the Board represents.

These data are submitted in duplicate to the office of the Secretary of the Advisory Board for Medical Specialties.

An application for election to membership in the Advisory Board and the data listed above are referred immediately for review by the Committee on Standards and Examinations of the Advisory Board. Upon approval by the Committee incorporation is then completed and a statement of this filed with the Secretary. Action on the application will be taken at the succeeding meeting of the Advisory Board for Medical Specialties and each examining Board as elected will be recommended to the Council on Medical Education and Hospitals of the American Medical Association for official recognition. One of the two sets of data submitted is forwarded to the Council on Medical Education and Hospitals of the American Medical Association with the Advisory Board's recommendation. Examination and certification of applicants in the specialty may begin immediately upon the special board being given such approval.

Communications should be addressed to the secretary.

CONSTITUTION AND BY-LAWS

Adopted at Organization Meeting, February 11, 1934

ARTICLE I

NAME

The name of this organization shall be "The Advisory Board for Medical Specialties."

ARTICLE II

PURPOSE

This Board shall act in an advisory capacity to such organization as may seek its advice concerning the coordination of the education and certification of medical specialists. No action taken by this Board shall be binding upon any member organizations.

ARTICLE III

MEMBERSHIP

Section I

This Board shall be composed of two representatives from each of the examining boards of the medical specialties and such other national organizations as are interested in education, examination, or certification of medical specialists.

Section II—Original Membership

At the time of the organization, this Board shall be composed of representatives from each of the following bodies:

The American Board of Ophthalmology.

The American Board of Otolaryngology

The American Board of Obstetrics and Gynecology

The American Board of Dermatology and Syphilology

The Association of American Medical Colleges

The National Board of Medical Examiners

The Federation of State Medical Boards of the U. S. A.

The American Hospital Association

The Council on Medical Education and Hospitals of the American Medical Association

Section III—Additional Membership

To be eligible for representation in this Board an examining board in a specialty must be composed of members elected from or appointed by Societies recognized by this Board as National Societies in that specialty together with representation from the related Section of the American Medical Association. Upon being accepted by this Advisory Board the board in question will be recommended to the American Medical Association as being qualified for recognition by that Association.

Section IV—Quorum

A quorum at any meeting shall consist of a majority of the official representatives to the Board and at least one-third of the membership organizations shall be represented. Each member organization shall be entitled to two votes.

ARTICLE IV

OFFICERS AND STANDING COMMITTEES

Section I—Officers

The officers of this Board shall be (a) President, (b) Vice President, (c) Secretary-Treasurer. These officers shall be elected at the annual meeting each year.

Section II—Standing Committees

The standing committees shall be as follows:

1. The Executive Committee

2. Standards and Examinations

3. Finance

The Executive Committee shall consist of the President, Vice President, Secretary-Treasurer, and two members elected at the annual meetings. No organization should have more than one member on the Executive Committee. The President shall be the Chairman of the Executive Committee. The other standing committees shall be appointed by the President.

ARTICLE V

AMENDMENTS TO THE CONSTITUTION

Amendments to this constitution may be made by a majority vote of the official representatives present at any annual meeting provided that thirty days' notice of the proposed amendment has been given each member of the Board.

BY-LAWS

ARTICLE I

DUTIES OF OFFICERS

Section I

The President shall preside at all meetings of the Board, shall act as Chairman of the Executive Committee, and shall appoint all other standing committees. He shall call meetings of the Executive Committee at such time and place as may be deemed necessary.

Section II

The Vice President shall assume the duties of the President in his absence.

Section III

The Secretary-Treasurer shall perform the usual duties of this office.

ARTICLE II

EXECUTIVE COMMITTEE

The Executive Committee shall carry out the policies and activities decided upon by the Board. It shall have an interim authority to initiate policies subject to approval by the Board at the annual or any special meeting. The two elected members shall serve for two years, the terms of office terminating in alternate years.

ARTICLE III

MEETINGS

Section I

There shall be an annual meeting at such time and place as the Board may determine. A special meeting may be called by the President upon ten days' notice to all members stating time, place and purpose of such meetings. The Executive Committee may present other business for consideration.

Section II

The Executive Committee shall meet subject to the call of the President.

Section III

Robert's Rules of Order shall be followed except where they conflict with this Constitution and By-Laws.

ARTICLE IV

AMENDMENTS TO THE BY-LAWS

Amendments to these by-laws may be made at any regular or special meeting of the Board.

DESCRIPTION OF MEDICAL SCHOOLS

ARKANSAS

Little Rock

UNIVERSITY OF ARKANSAS SCHOOL OF MEDICINE, 1209 McAlmont Street.—Organized in 1879 as the Medical Department of Arkansas Industrial University. Present title in 1899. In 1911 the College of Physicians and Surgeons united with it and it became an integral part of the University of Arkansas. The first class was graduated in 1880. Clinical teaching was suspended in 1918 but resumed in 1923. Coeducational since organization. The faculty consists of 26 professors and 82 lecturers and assistants, total 108. The curriculum covers four years of nine months each. Entrance requirements are two years of collegiate work. The B.S. degree in medicine is conferred at the end of the second year. The fees for the four years for residents of Arkansas are \$275; nonresidents are charged \$155 additional each year. The registration for 1938-1939 was 282; graduates, 72. The next session begins Sept. 27, 1939, and ends June 4, 1940. The Dean is Stuart P. Cromer, M.D.

CALIFORNIA

Berkeley-San Francisco

UNIVERSITY OF CALIFORNIA MEDICAL SCHOOL, University Campus, Berkeley; Medical Center, San Francisco.—Organized in 1862 as the Land Medical College. The first class graduated in 1864. In 1872 became the Medical Department of the University of California. In 1909, by legislative enactment, the College of Medicine of California. In 1914, the College of Medicine of California. In 1915 the Hahnemann pathic materia medica, and therapeutics were merged, and elective chairs in homeo- since organization. Three years of collegiate work are required for admis- sion. The work of the first year is given at Berkeley and that of the last three years at San Francisco. The faculty is composed of 154 pro- fessors and 259 associates and assistants, a total of 413. The course covers four years of eight months each, and an additional fifth year con- sisting of an internship in a hospital or of special work in a department of the medical school. Fees for the four years, respectively, for residents of California are \$277, \$240, \$235 and \$235; nonresidents are charged \$300 additional each year. The registration for 1938-1939 was 245; graduates, 63. The next session begins Aug. 28, 1939, and ends May 5, 1940. The Dean is Langley Porter, M.D., San Francisco.

Loma Linda-Los Angeles

COLLEGE OF MEDICAL EVANGELISTS.—Organized in 1909. The first class graduated in 1914. The laboratory departments are at Loma Linda, the clinical departments at Los Angeles. Coeducational since organiza- tion. The faculty is composed of 57 professors and 272 associates, assistants and instructors, a total of 329. The course covers a period of four years of nine months each and an additional year consisting of an internship in an approved hospital. Sixty-four semester hours of collegiate work are required for admission. The total fees are respectively, \$545, \$535, \$545 and \$555. The registration for 1938-1939 was 340; graduates, 109. The next session begins Sept. 4, 1939, and ends June 9, 1940. The Dean is W. E. Macpherson, M.D., Loma Linda; and the Associate Dean is E. H. Risley, M.D., Los Angeles.

Los Angeles

UNIVERSITY OF SOUTHERN CALIFORNIA SCHOOL OF MEDICINE, 3551 University Avenue.—Organized in 1885 as the University of Southern California College of Medicine. First class graduated in 1888. In 1908 it became the Medical Department of the University of California in Los Angeles. In 1909 the College of Physicians and Surgeons, estab- lished in 1904, became the Medical Department of the University of Southern California. Its activities were suspended in 1920; reorganized and 150 instructors, assistants and others, a total of 299. An internship is required for graduation. Three years of collegiate work are required for admission. Coeducational since organization. Annual fees amount to \$452. The registration for 1938-1939 was 199; graduates, 44. The next session begins Sept. 18, 1939, and ends June 8, 1940. The Dean is Paul S. McKibben, Ph.D.

San Francisco

STANFORD UNIVERSITY SCHOOL OF MEDICINE, 2398 Sacramento Street, San Francisco.—Organized in 1908, when, by agreement, the interests of Cooper Medical College were taken over. The first class graduated in 1913. Coeducational since organization. The faculty consists of 127 professors and 153 lecturers, assistants and others, a total of 280. Three years of collegiate work are required for admission. The course covers four years of eight and one-half months, each, plus a fifth year of intern work. The fees for the four years, respectively, are \$470, \$446, \$364 and \$364. The registration for 1938-1939 was 237; graduates, 57. The next session begins September 26, 1939, and ends June 16, 1940. The Dean is Loren Roscoe Chandler, M.D.

COLORADO

Denver

UNIVERSITY OF COLORADO SCHOOL OF MEDICINE, 4200 East Ninth Avenue.—Organized in 1883. Classes were graduated in 1885 and in all subsequent years except 1898 and 1899. Denver and Gross College of Medicine was merged, Jan. 1, 1911. Coeducational since organization. The faculty is composed of 57 professors and 130 lecturers, instructors and assistants, a total of 187. The course covers four years of nine

months each. The entrance requirements are three years of collegiate work. The fees for residents of Colorado are, respectively, \$301, \$306, \$291 and \$286. Nonresidents are charged \$235 additional each year. The registration for 1938-1939 was 209; graduates, 49. The next session begins Sept. 25, 1939, and ends June 10, 1940. The Dean is Maurice H. Rees, M.D.

CONNECTICUT

New Haven

YALE UNIVERSITY SCHOOL OF MEDICINE, 333 Cedar Street.—Chartered in 1810 as the Medical Institution of Yale College. Organized in 1812; instruction began in 1813; first class graduated in 1814. A new charter in 1879 changed the name to the Medical Department of Yale College. In 1884, the Connecticut Medical Society surrendered such authority as had been granted by the first charter. In 1887, Yale College became Yale University. Coeducational since 1916. The faculty consists of 167 professors and 217 lecturers and assistants, a total of 384. The requirements for admission are three years of collegiate work. The course covers four years of nine months each. The fees are respectively, \$505, \$500, \$500, and \$520. The registration for 1938-1939 was 200; graduates, 43. The next session begins Sept. 25, 1939, and ends June 12, 1940. The Dean is Stanhope Bayne-Jones, M.D.

DISTRICT OF COLUMBIA

Washington

GEORGETOWN UNIVERSITY SCHOOL OF MEDICINE, 3900 Reservoir Road, N.W.—Organized in 1851. First class graduated in 1852. The faculty is composed of 63 professors, 45 associate professors, 28 assistant pro- fessors and 119 instructors; total 255. Three years of collegiate work are required for admission. The course of study covers four terms of eight and one-half months each. The present fees for each of the four sessions are \$500. The registration for 1938-1939 was 336; graduates 73. The next session begins Sept. 18, 1939, and ends June 10, 1940. The Dean is David V. McCauley, S.J., Ph.D.

GEORGE WASHINGTON UNIVERSITY SCHOOL OF MEDICINE, 1335 H Street, N.W.—Organized in 1825 as the Medical Department of Colum- bian College. Also authorized to use the name National Medical College. Classes were graduated in 1826 and in all subsequent years except in 1834 to 1838, and 1861 to 1863, inclusive. The original title was changed to Medical Department of Columbian University in 1873. In 1903 it absorbed the National University Medical Department. In 1904, by an Act of Congress, the title of George Washington University was granted to the institution. Coeducational since 1884. The faculty is composed of 70 professors and 124 instructors, demonstrators and assis- tants, a total of 194. Two years of collegiate work are required for admission. The course covers four years of thirty-six weeks each. The fees for each of the four years are \$550. The registration for 1938-1939 was 243; graduates, 56. The next session begins Sept. 25, 1939, and ends June 12, 1940. The Dean is Walter A. Bloedorn, M.D.

HOWARD UNIVERSITY COLLEGE OF MEDICINE, Fifth and W Streets, N.W.—Chartered in 1867. Organized in 1869. The first class graduated in 1871. Coeducational since organization. Negro students compose a majority of those in attendance. The faculty comprises 28 professors and 68 lecturers and assistants, 96 in all. The admission requirements are at least two years of collegiate work. The course covers four years of thirty-three weeks each. The fees are, respectively, \$269, \$269, \$259 and \$266. Registration for 1938-1939 was 129; graduates, 30. The next session begins Sept. 25, 1939, and ends June 7, 1940. The Dean is Numa P. G. Adams, M.D.

GEORGIA

Atlanta

EMORY UNIVERSITY SCHOOL OF MEDICINE, 50 Armstrong Street.—Organized in 1854 as the Atlanta Medical College. Classes graduated in 1855 to 1861, when it suspended. Reorganized in 1865. A class gradu- ated in 1865 and each subsequent year except 1874. In 1898 it merged with the Southern Medical College (organized in 1878), taking the name of Atlanta College of Physicians and Surgeons. In 1913 it merged with the Atlanta School of Medicine (organized in 1905), reassuming the name of Atlanta Medical College. Became the Medical Department of Emory University in 1915; assumed present title in 1917. Three years of col- legiate work are required for admission. The faculty consists of 18 profes- sors and 180 associates and assistants, a total of 198. The course of study is four years of thirty-two weeks each. The fees for each of the four years are \$338. The registration for 1938-1939 was 208; graduates, 47. The next session begins Sept. 25, 1939, and ends June 10, 1940. The Dean is Russell H. Oppenheimer, M.D.

Augusta

UNIVERSITY OF GEORGIA SCHOOL OF MEDICINE, University Place.—Organized in 1828 as the Medical Academy of Georgia, the name being changed to the Medical College of Georgia in 1829. Since 1873 it has been known as the Medical Department of the University of Georgia, the name being changed July 1, 1933, to the University of Georgia School of Medicine. Property transferred to the University of Georgia in 1911. Classes were graduated in 1833 and all subsequent years except 1862 and 1863. Coeducation was begun in 1920. The faculty includes 60 professors and 29 assistants, 89 in all. Three years of collegiate work are required for admission. The course is four years of thirty-four weeks each. The fees for each of the four years are \$185 for residents of Georgia, and \$365 for nonresidents. The registration for 1938-1939 was 157; graduates, 31. The next session begins Sept. 25, 1939, and ends June 10, 1940. The Dean is G. Lombard Kelly, M.D.

ILLINOIS

Chicago

LOYOLA UNIVERSITY SCHOOL OF MEDICINE, 706 South Wolcott Avenue.—Incorporated in 1915 as the Bennett Medical College, and operated as an organic part of Loyola University, by virtue of an agreement entered into with the trustees of Bennett Medical College. Present title assumed in 1917. The Chicago College of Medicine and Surgery was purchased in 1917. The first class graduated in 1916. Coeducational. Three years of collegiate work are required for admission. The course of study is five years, including an internship. The faculty is composed of 120 in professorial rank and 143 others, a total of 263. The fees for each year are \$510, \$450, \$366 and \$330 respectively. The enrolment for 1938-1939 was 350; graduates, 110. Next session for juniors and seniors begins September 11, 1939, for freshmen and sophomores, Sept. 25, 1939, and ends June 8, 1940. The Dean is Louis D. Moorhead, M.D.

NORTHWESTERN UNIVERSITY MEDICAL SCHOOL, 303 East Chicago Avenue.—Organized in 1859 as the Medical Department of Lind University. First class graduated in 1860. In 1864 it became independent as the Chicago Medical College. It united with Northwestern University in 1869 but retained the name of Chicago Medical College until 1891, when the present title was taken. Became an integral part of Northwestern University in 1905. Coeducational since 1926. The faculty comprises 136 professors, 335 associates and instructors, a total of 471. The requirement for admission is three years of collegiate work. The B.S. degree in medicine may be conferred before the end of the senior year. The course covers four years of eight and one-half months each and a fifth year spent in an approved hospital as an intern or in other practical work. The total fees are \$414 each year. The registration for 1938-1939 was 556; graduates, 154. The next session begins Sept. 26, 1939, and ends June 15, 1940. The Dean is Irving S. Cutter, M.D.

THE UNIVERSITY OF CHICAGO MEDICAL SCHOOLS.—The Medical Schools include (a) The School of Medicine of the Division of the Biological Sciences and (b) Rush Medical College, both of which are organized within the Division of the Biological Sciences. The first two years of the medical course for both are given in the School of Medicine of the Division of the Biological Sciences and the last two years are given either in the School of Medicine of the Division of the Biological Sciences or in Rush Medical College.

The School of Medicine of the Division of the Biological Sciences, Fifty-Eighth Street and Ellis Avenue.—Organized in 1924. The work of the first two years of the medical course has been given on the Quadrangles since 1899, in cooperation with Rush Medical College, and that of the third and fourth clinical years has been given since 1924 with the organization of this medical school and the construction on the Quadrangles of the University hospitals and clinics. Coeducational. The faculty is composed of 97 professors, 162 associates, instructors and others, a total of 259. The requirements for admission are three years of collegiate work. The B.S. degree in medicine may be obtained during the second year. The curriculum covers twelve quarters of work. Students are admitted at the beginning of the spring, summer and autumn quarters. Sixty-five students are admitted to first year classes in each calendar year. The tuition fee for each of the four years is \$450. The registration for 1938-1939 was 297; graduates, 51. The next session begins Oct. 2, 1939, and ends June 13, 1940.

Rush Medical College, 1758 West Harrison Street.—Chartered in 1837; held first class in 1843. First class graduated in 1844. In 1887 the college became the medical department of Lake Forest University, retaining, however, its self government. This relation was dissolved in April, 1898, and in the same month affiliation with the University of Chicago was established. Coeducational since 1898. In May 1924, by a new contract, the University of Chicago took over the work of Rush Medical College as a department of the University. Thereafter only clinical work has been offered by Rush Medical College. The work of the first two years is given on the University Quadrangles. Three years of collegiate work are required for admission. The year is divided into four quarters of twelve weeks each; the completion of the work of three of these quarters gives credit for a college year. The requirements for the degree consists of twelve full quarters of work. The faculty is composed of 137 professors, 172 associates, instructors and others, a total of 309. The tuition fee is \$450 yearly. The registration for 1938-1939 was 223; graduates, 111. The next session begins Oct. 2, 1939, and ends June 12, 1940. The school is in session all year except the month of September.

All correspondence relating to general policies should be addressed to W. H. Taliaferro, Ph.D., Dean of the Division of the Biological Sciences, or to A. C. Bachmeyer, M.D., Associate Dean of the Division; that relating to Rush Medical College should be addressed to Emmet B. Bay, M.D., Associate Dean of the Division of the Biological Sciences (Rush Medical College); and that pertaining to student questions should be addressed to B. C. H. Harvey, M.D., Dean of Medical Students.

UNIVERSITY OF ILLINOIS COLLEGE OF MEDICINE, 1853 West Polk Street.—Organized in 1882 as the College of Physicians and Surgeons. The first class graduated in 1883. It became the Medical Department of the University of Illinois by affiliation in 1897. Relationship with the university was cancelled in June 1912, and was restored in March 1913, when the present title was assumed. Coeducational since 1898. Three years of collegiate work are required for admission. The curriculum covers four years of thirty-two weeks each, and a year of internship in an approved hospital. The B.S. degree in medicine is conferred at the end of the second year. The faculty is composed of 143 professors and 325 associates, instructors and assistants, a total of 468. The tuition is \$150 a year for students who are residents of Illinois; \$225 a year for nonresident students. The registration for 1938-1939 was 638; graduates 160. The next session begins Sept. 25, 1939, and ends June 7, 1940. The Dean is David J. Davis, M.D.

INDIANA

Bloomington-Indianapolis

INDIANA UNIVERSITY SCHOOL OF MEDICINE.—Organized in 1903 but did not give all the work of the first two years of the medical course until 1905. In 1907, by union with the State College of Physicians and Surgeons, the complete course in medicine was offered. In 1908 the Indiana Medical College, which was formed in 1905 by the merger of the Medical College of Indiana (organized in 1878), the Central College of Physicians and Surgeons (organized in 1879), and the Fort Wayne College of Medicine (organized in 1879) merged into it. The first class was graduated in 1908. Coeducational since organization. The faculty consists of 270 professors, lecturers, associates and assistants. Three years of collegiate work are required for admission. The B.S. degree in medicine is conferred. The work of the first year is given at Bloomington and the work of the next three years at Indianapolis. The regular fee for the medical course for all four years is \$217 a year for residents of Indiana, and \$423 for nonresidents. The registration for 1938-1939 was 449; graduates, 104. The next session begins Sept. 16, 1939, and ends June 3, 1940. The Dean at Bloomington is Burton D. Myers, M.D., and the Dean at Indianapolis is Willis D. Gatch, M.D.

IOWA

Iowa City

STATE UNIVERSITY OF IOWA COLLEGE OF MEDICINE, University Campus.—Organized in 1869. First session began in 1870. First class graduated in 1871. Absorbed Drake University College of Medicine in 1913. Coeducational since 1870. The faculty is made up of 56 professors, 74 lecturers, demonstrators and assistants, a total of 130. Three years of collegiate work are required for admission. The B.A. degree in the combined course of liberal arts and medicine is conferred. The course of study covers four years of thirty-four weeks each. The tuition fee is \$196 each year for residents of Iowa and \$460 for nonresidents. The registration for 1938-1939 was 308; graduates, 86. The next session begins Sept. 21, 1939, and ends June 3, 1940. The Dean is Ewen Murchison MacEwen, M.D.

KANSAS

Lawrence-Kansas City

UNIVERSITY OF KANSAS SCHOOL OF MEDICINE.—Organized in 1880. It offered only the first two years of the medical course until 1905, when it merged with the Kansas City (Mo.) Medical College, founded in 1869, the College of Physicians and Surgeons, founded in 1894, and the Medico-Chirurgical College, founded in 1897. Absorbed Kansas Medical College in 1913. First class graduated in 1906. The clinical courses are given at Kansas City. Coeducational since 1880. The faculty includes 62 professors and 142 instructors, assistants and others, a total of 204. The requirement for admission is three years of collegiate work. The B.S. degree in medicine is conferred at the end of the second year. The course covers four years of nine months each. The total fees for residents of the state are, respectively, \$137, \$163, \$155 and \$157. For nonresidents the fees are, respectively, \$202, \$343, \$405 and \$407. The registration for 1938-1939 was 291; graduates, 70. The next session begins Sept. 21, 1939, and ends June 10, 1940. The Dean is H. R. Wahl, M.D., Kansas City.

KENTUCKY

Louisville

UNIVERSITY OF LOUISVILLE SCHOOL OF MEDICINE, 101 West Chestnut Street.—Organized in 1837 as Louisville Medical Institute. The first class graduated in 1838, and a class graduated each subsequent year except 1863. In 1846 the name was changed to University of Louisville Medical Department. In 1907 it absorbed the Kentucky University Medical Department; in 1908, the Louisville Medical College, the Hospital College of Medicine and the Kentucky School of Medicine. In 1922 it changed its name to the University of Louisville School of Medicine. Coeducational since organization. Two years of collegiate work are the minimum requirement for admission. Preference is given applicants with a degree or three college years leading to a degree. The faculty numbers 77 professors, and 107 assistants, instructors and others, a total of 184. Course covers four years of thirty-two weeks each, exclusive of vacations and examinations. Fees are, respectively, \$450, \$450, \$450 and \$460. The registration for 1938-1939 was 338; graduates, 87. The next session begins Sept. 14, 1939, and ends June 1, 1940. The Dean is John Walker Moore, M. D.

LOUISIANA

New Orleans

LOUISIANA STATE UNIVERSITY SCHOOL OF MEDICINE, 1542 Tulane Avenue.—Organized January 1931 as Louisiana State University Medical Center. Present title in 1939. Coeducational. First session October 1931. Students of first and third year. Faculty comprises 43 professors and 160 assistant professors, instructors and assistants, a total of 203. Course covers four years of no less than 32 weeks each and one year of Course covers four years of no less than 32 weeks each and one year of a general rotation or laboratory internship in an approved hospital. A minimum of three years' collegiate work is required for admission. Total fees, \$132 each year for residents of Louisiana; additional tuition of \$450 each year for nonresidents. The registration for 1938-1939 was 223; graduates, 59. The next session begins Sept. 11, 1939, and ends May 31, 1940. The Dean is Rigney D'Aunoy, M.D.

TULANE UNIVERSITY OF LOUISIANA SCHOOL OF MEDICINE, 1411 Tulane Avenue.—Organized in 1834 as the Medical College of Louisiana. Classes were graduated in 1835 and in all subsequent years except 1863-1865, inclusive. It was transferred to the Medical Department of the

MEDICAL EDUCATION

827

University of Louisiana in 1847, and became the Medical Department of the Tulane University of Louisiana in 1884. Present title in 1913. Coeducational since 1915. The faculty comprises 34 professors and 198 associate and assistant professors, instructors and assistants, a total of 232. The course covers four years of thirty-two weeks each. A minimum of three years of collegiate work is required for admission. Total fees are, respectively, \$457, \$447, \$437 and \$447. The registration for 1938-1939 was 478; graduates, 110. The next session begins Sept. 22, 1939, and ends June 5, 1940. The Dean is Charles C. Bass, M.D.

MARYLAND Baltimore

JOHNS HOPKINS UNIVERSITY SCHOOL OF MEDICINE. 710 North Washington Street.—Organized in 1887. Offered preliminary course only until 1893. The first class graduated in 1897. Coeducational since organization. The faculty consists of 68 professors and 389 instructors, assistants and others, a total of 457. The requirement for admission is a collegiate degree. The course extends over four years of eight and one-half months each. The total fees are, respectively, \$621, \$620, \$620 and \$620. The registration for 1938-1939 was 279; graduates, 73. The next session begins Sept. 26, 1939, and ends June 4, 1940. The Dean is Alan M. Chesney, M.D.

UNIVERSITY OF MARYLAND SCHOOL OF MEDICINE AND COLLEGE OF PHYSICIANS AND SURGEONS. Lombard and Greene Streets.—Organized in 1807 as the College of Medicine of Maryland. The first class graduated in 1810. In 1812 it became the University of Maryland School of Medicine. Baltimore Medical College was merged with it in 1913. In 1915 the present name assumed. Coeducational since 1918. The faculty consists of 41 professors, 75 associate and assistant professors, and 178 instructors and assistants, a total of 294. Three years of collegiate work are required for admission. The course covers four years of eight months each. The fees are, respectively, \$485, \$475, \$475 and \$490 for residents of the state; for nonresidents the fees are \$150 additional each year. The registration for 1938-1939 was 371; graduates, 88. The next session begins Sept. 21, 1939, and ends June 1, 1940. The Dean is J. M. H. Rowland, M.D.

MASSACHUSETTS Boston

BOSTON UNIVERSITY SCHOOL OF MEDICINE. 80 East Concord Street.—Organized in 1873 as a homeopathic institution. In 1874 the New England Female Medical College, founded in 1848, was merged into it. The first class was graduated in 1874. Became nonsectarian in 1918. Coeducational since organization. Three years of collegiate work are required for admission. The faculty includes 26 professors, 171 associates and others, a total of 197. The course covers four years. Total fees for each of the four years, respectively, are \$479, \$475, \$425, \$440. The registration for 1938-1939 was 201; graduates, 49. The next session begins September 21, 1939, for 1st, 2d and 3d year students, and September 11, 1939, for 4th year students, and ends June 10, 1940. The Dean is Alexander S. Begg, M.D.

HARVARD MEDICAL SCHOOL. 25 Shattuck Street.—Organized in 1782. The first class graduated in 1788. It has a faculty of 156 professors and 443 other instructors and assistants, a total of 599. Two years of collegiate work are required for admission. The total fees for each of the four years are \$420, plus \$5 the first year for matriculation. The registration for 1938-1939 was 517; graduates, 130. The next session begins Sept. 25, 1939, and ends June 20, 1940. The Dean is C. Sidney Burwell, M.D.

TUFTS COLLEGE MEDICAL SCHOOL. 416 Huntington Avenue.—Organized in 1893 as the Medical Department of Tufts College. The first class graduated in 1894. Coeducational since 1894. It has a faculty of 82 professors and 296 assistants, lecturers and others, a total of 378. A bachelor's degree is required for admission. The course covers four years of eight months each. The total fees for each of the four years are \$512, \$507, \$507 and \$517. The registration for 1938-1939 was 396; graduates, 110. The next session begins Sept. 20, 1939, and ends June 17, 1940. The Dean is A. Warren Stearns, M.D.

MICHIGAN Ann Arbor

UNIVERSITY OF MICHIGAN MEDICAL SCHOOL.—Organized in 1850 as the University of Michigan Department of Medicine and Surgery. The first class graduated in 1851. Present title assumed in 1915. Coeducational since 1870. It has a faculty of 28 professors, 18 associate professors, 29 assistant professors, 131 assistants, instructors and lecturers; total of 206. The entrance requirements are ninety semester hours. The curriculum covers four years of nine months each. The total fees for Michigan students are \$220 for each of the four years, respectively; for nonresidents, \$350 a year. The registration for 1938-1939 was 469; graduates, 102. The next session begins Sept. 23, 1939, and ends June 15, 1940. The Dean is A. C. Furstenberg, M.D.

WAYNE UNIVERSITY COLLEGE OF MEDICINE. 1516 St. Antoine Street.—Organized as the Detroit College of Medicine in 1885 by consolidation of Detroit Medical College, organized in 1868, and the Michigan College of Medicine, organized in 1880. Reorganized with the title of Detroit College of Medicine and Surgery in 1913. The first class graduated in 1886. In 1918 it became a municipal institution under the control of the Detroit Board of Education. In 1934 the name was changed by action of the Detroit Board of Education to Wayne University College of Medicine, as a part of the program of consolidation of the Detroit City Colleges into a university system. Coeducational since 1917. Entrance requirement is an academic degree or 90 semester hours of academic credit with "combined degree" guaranteed by school of arts and sciences.

The faculty consists of 48 professors, 253 lecturers and others, a total of 303. The course covers four years of nine months each and a fifth year of intern work. The total fees for each of the first four years are, for Wayne County residents \$325, and for nonresidents outside of Wayne County \$425; for the fourth year a diploma fee of \$10.00. The registration for 1938-1939 was 237; graduates, 76. The next session begins September 18, 1939, and ends June 15, 1940. The Associate Dean is William J. Stapleton Jr., M.D.

MINNESOTA Minneapolis

UNIVERSITY OF MINNESOTA MEDICAL SCHOOL.—Organized in 1883 as the University of Minnesota College of Medicine and Surgery, reorganized in 1888 by absorption of St. Paul Medical College and Minnesota Hospital College. The first class graduated in 1889. In 1908 the Minneapolis College of Physicians and Surgeons, organized in 1883, was merged. In 1909 the Homeopathic College of Medicine and Surgery was merged. Present title in 1913. Coeducational since organization. The faculty includes 90 professors and 238 instructors, a total of 328. The curriculum covers four years of nine months each, and a year's internship in an approved hospital. The school is operated on the four-quarter plan. The entrance requirements are three years of university work, which must include six semester credits of rhetoric, eight semester credits of physics; thirteen credits of general chemistry, qualitative and quantitative analysis, organic and physical chemistry; eight credits of general zoology and genetics and eugenics; four credits of general psychology, and a reading knowledge of scientific German, with a "C" average in all subjects and in the sciences. Students are required to meet the requirements for a degree of B.S. or B.A. before receiving the degree of Bachelor of Medicine (M.D.), which is conferred at the end of the fourth year course. The M.D. degree is conferred after a year of intern work, is completed and examinations passed. Total fees are \$243 for residents and \$393 for nonresidents, each year of three quarters. The registration for 1938-1939 was 489; graduates, 123. The next session begins Oct. 2, 1939, and ends June 15, 1940. The Dean is Harold S. Diehl, M.D.

MISSOURI St. Louis

ST. LOUIS UNIVERSITY SCHOOL OF MEDICINE. 1402 South Grand Boulevard. Organized in 1901 as the Marion-Sims-Beaumont Medical College by union of Marion-Sims Medical College, organized in 1890, and Beaumont Hospital Medical College, organized in 1886. First class graduated in 1902. It became the Medical School of St. Louis University in 1903. The faculty is composed of 77 professors and 252 instructors and assistants, a total of 329. The completion of three years of college study is the minimum admission requirement but students presenting meritorious credits in excess of the minimum are accepted by preference. The curriculum covers four years of thirty-two weeks each. The summer session optional and offers courses academically equivalent to those in the regular session. The total fees are, respectively, \$525, \$525, \$525 and \$455. The registration for 1938-1939 was 441; graduates, 123. The next session begins Sept. 19, 1939, and ends June 1, 1940. The Dean is Alphonse M. Schmitt, S.J., Ph.D.

WASHINGTON UNIVERSITY SCHOOL OF MEDICINE. Kingshighway and Euclid Avenue.—Organized in 1842 as the Medical Department of St. Louis University. The first class graduated in 1843. In 1855 it was chartered as an independent institution under the name of St. Louis Medical College. In 1891 it became the Medical Department of Washington University. In 1899 it absorbed the Missouri Medical College. Coeducational since 1818. The faculty comprises 114 professors and 223 lecturers, instructors and others, a total of 337. Four years of collegiate work are required for admission. The B.S. degree in medicine is conferred at the end of the third or fourth year. The course is four years and \$424. The registration for 1938-1939 was 347; graduates, 95. The next session begins Sept. 28, 1939, and ends June 11, 1940. The Dean is Philip A. Shaffer, Ph.D.

NEBRASKA Omaha

CREIGHTON UNIVERSITY SCHOOL OF MEDICINE. 306 North Fourteenth Street.—Organized in 1892 as the John A. Creighton Medical College. The first class graduated in 1893. Present title in 1921. Coeducational since organization. It has a faculty of 61 professors and 77 instructors, lecturers and assistants, a total of 138. Two years of collegiate work are required for admission. The B.S. degree in medicine is conferred at the end of the second year. The curriculum covers four years of eight months each. The total fees for the four years are, respectively, \$393, \$348 and \$356, and \$100 additional each year for nonresidents. The registration for 1938-1939 was 246; graduates, 57. The next session begins Sept. 19, 1939, and ends May 31, 1940. The Dean is Bryan M. Riley, M.D.

UNIVERSITY OF NEBRASKA COLLEGE OF MEDICINE. Forty-Second Street and Dewey Avenue.—Organized in 1881 as the Omaha Medical College. The first class graduated in 1882. It became the Medical Department of Omaha University in 1891. In 1902 it affiliated with the University of Nebraska, with the present title. The instruction of the first two years was given at Lincoln and of the last two at Omaha until 1913, when the work of all four years was transferred to Omaha. Coeducational since 1882. The faculty is composed of 72 professors and 55 lecturers and instructors, a total of 127. Three years of collegiate work are required for admission. The B.S. degree in medicine is conferred at the end of the second year. The fees for the four years, respectively, are \$219, \$214, \$214 and \$214. The registration for 1938-1939 was 316; graduates, 70. The next session begins Sept. 25, 1939, and ends June 3, 1940. The Dean is C. W. M. Forster, M.D.

NEW YORK

Albany

ALBANY MEDICAL COLLEGE, 47 New Scotland Avenue.—Organized in 1838. The first class graduated in 1839. It became the Medical Department of Union University in 1873. In 1915 Union University assumed educational control. Coeducational since 1915. The faculty is composed of 69 professors and 103 instructors, assistants and others, a total of 172. A collegiate degree is required for admission. The curriculum covers four years of eight months each. The total fees are, respectively, \$455, \$430, \$415 and \$415. The registration for 1938-1939 was 112; graduates, 23. The next session begins Sept. 18, 1939, and ends June 10, 1940. The Dean is R. S. Cunningham, M.D.

Brooklyn

LONG ISLAND COLLEGE OF MEDICINE, 350 Henry Street.—Organized in 1858 as the Long Island College Hospital. The first class graduated in 1860 and the last class in 1930. Reorganized with a new charter in 1930 as the present institution. The first class graduated in 1931. Coeducational. It has a faculty of 119 professors, associate, assistant, clinical and assistant clinical professors, and 173 lecturers, associates, instructors, assistants and others, a total of 292. Ninety semester hours of collegiate work are required for admission. The course covers four years. The total fee for each of the four years is \$610. The registration for 1938-1939 was 363; graduates, 90. The next session begins Sept. 11, 1939, for the fourth year and Sept. 25, for the other years, and ends June 8, 1940. The Dean is Jean Alonzo Curran, M.D.

Buffalo

UNIVERSITY OF BUFFALO SCHOOL OF MEDICINE, 24 High Street.—Organized in 1846. The first class graduated in 1847. It absorbed the Medical Department of Niagara University in 1898. Coeducational since organization. The faculty is composed of 87 professors and 198 associates, assistants and others, a total of 285. Two years of collegiate work are required for admission. The course covers four years of eight months each. The total fees are, respectively, \$530, \$525, \$520 and \$530. The registration for 1938-1939 was 237; graduates, 63. The next session begins Oct. 2, 1939, and ends June 8, 1940. The Dean is Edward W. Koch, M.D.

New York

COLUMBIA UNIVERSITY COLLEGE OF PHYSICIANS AND SURGEONS, 630 West One Hundred and Sixty-Eighth Street.—The medical faculty of Columbia College, then known as King's College, was organized in 1767. Instruction was interrupted by the War of the Revolution. The faculty was reestablished in 1792 and merged in 1814 with the College of Physicians and Surgeons, which had received an independent charter in 1807. In 1860 the College of Physicians and Surgeons became the Medical Department of Columbia College. This merger became permanent by legislative enactment in 1891. Columbia College became Columbia University in 1896. The medical school has been coeducational since 1917. The faculty is composed of 252 professors and 524 instructors, demonstrators and others, a total of 776. Three years of collegiate work are required for admission. The work covers four years of eight months each. The total fees are, respectively, \$545, \$530, \$530 and \$550. The registration for 1938-1939 was 406; graduates, 89. The next session begins Sept. 21, 1939, and ends June 4, 1940. The Dean is Willard C. Rappleye, M.D.

NEW YORK MEDICAL COLLEGE, FLOWER AND FIFTH AVENUE HOSPITALS, 1 East 105th Street.—Organized in 1858. Incorporated in 1860 as the Homeopathic Medical College of the State of New York. The title New York Homeopathic Medical College was assumed in 1869; the title New York Homeopathic Medical College and Hospital in 1887; the title New York Homeopathic Medical College and Flower Hospital in 1908; the title New York Medical College and Flower Hospital in 1936; the present title of New York Medical College, Flower and Fifth Avenue Hospitals, June 22, 1938. The first class graduated in 1861. Coeducational since 1919. A baccalaureate degree or its equivalent required for admission. The course covers four years of eight months each. It has a faculty of 68 professors and associate professors, 25 assistant professors, and 228 lecturers and assistants, a total of 321. The total fees are, respectively, \$645, \$635, \$635 and \$665. The registration for 1938-1939 was 274; graduates 66. The next session begins Sept. 18, 1939, and ends June 7, 1940. The Dean is Claude A. Burrett, M.D.

NEW YORK UNIVERSITY COLLEGE OF MEDICINE, 477 First Avenue.—Organized in 1898 by the union of the New York University Medical College, organized in 1841, and the Bellevue Hospital Medical College, organized in 1861. Named University and Bellevue Hospital Medical College from 1898 to February 1935 when it was changed to New York University College of Medicine. First class graduated in 1899. Coeducational since 1919. The faculty is composed of 145 professors, associate, assistant, clinical and assistant clinical professors, and 367 lecturers, instructors and others, a total of 512. The course covers four years. Entrance requirements are that all candidates must have completed three full years of study in an approved college of arts and sciences. The fees for each of the four years are \$600. The next session begins Sept. 13, 1939, and ends June 5, 1940. The registration for 1938-1939 was 495; graduates, 124. The Dean is Currier McEwen, M.D.

CORNELL UNIVERSITY MEDICAL COLLEGE, 1300 York Avenue.—Organized in 1898. Coeducational since organization. The first year was given to approximately one-third of the class at Ithaca, but in 1938 this branch was discontinued and all work is now given in New York City. The faculty is composed of 126 professors and 306 assistants, lecturers, instructors, and others, a total of 432. All candidates for admission must be graduates of approved colleges or scientific schools, or seniors of approved colleges that will permit them to substitute the first year of this medical school for the fourth year of their college course and will confer on them the baccalaureate degree on the completion of the first

year's work. The fees are, respectively: \$620, \$510, \$515 and \$525. The registration for 1938-1939 was 286; graduates, 63. The next session begins Sept. 18, 1939, and ends June 5, 1940. The Dean is William S. Ladd, M.D.

Rochester

UNIVERSITY OF ROCHESTER SCHOOL OF MEDICINE AND DENTISTRY, 260 Crittenden Boulevard.—Organized in 1925 as the Medical Department of the University of Rochester. Coeducational since organization. The faculty is composed of 66 professors, 187 lecturers, assistants, instructors and others, a total of 253. The work embraces a graded course of four years of nine months each. Three years of collegiate work are required for admission. The total fees for each year are \$500. The registration for 1938-1939 was 188; graduates, 43. The next session begins Sept. 18, 1939, and ends June 15, 1940. The Dean is George Hoyt Whipple, M.D.

Syracuse

SYRACUSE UNIVERSITY COLLEGE OF MEDICINE, 766 Irving Avenue.—Organized in 1872, when the Geneva Medical College, chartered in 1834, was removed to Syracuse, under the title "The College of Physicians and Surgeons of Syracuse University." Present title assumed in 1875, when a compulsory three-year graded course was established. The first class graduated in 1873 and a class graduated each subsequent year. In 1889 the amalgamation with the university was made complete. Course extended to four years in 1896. Coeducational since organization. The faculty is composed of 48 professors and 167 associate and assistant professors, lecturers and instructors, a total of 215. Three years of a recognized college course are required for admission. The course covers four years of thirty-four weeks each. The fee for each of the first three years is \$500; for the fourth year, \$510. The enrollment for 1938-1939 was 177; graduates, 45. The next session begins Sept. 21, 1939, and ends June 3, 1940. The Dean is H. G. Weiskotten, M.D.

NORTH CAROLINA

Durham

DUKE UNIVERSITY SCHOOL OF MEDICINE.—Organized in 1925. The first class was admitted, Oct. 1, 1930. Coeducational. The faculty is composed of 12 professors and 137 associate and assistant professors, lecturers, instructors and assistants, a total of 149. The entrance requirements are ninety hours of collegiate work. The academic year consists of four quarters of eleven weeks each. Students either may study four quarters each year after the first year, and if satisfactory will receive the M.D. certificate after three and one quarter calendar years, or three quarters in each year, and if satisfactory will be graduated after four calendar years. The B.S. degree in medicine may be conferred for special work after six quarters. Students are urged to spend three years in hospital or laboratory work after graduation and must give assurance satisfactory to the executive committee that they will spend at least two years. The fees are \$450 for each year of three quarters. The registration for 1938-1939 was 263; graduates, 64. The next session begins Sept. 28, 1939, and ends June 8, 1940. The Dean is Wilbert C. Davison, M.D.

OHIO

Cincinnati

UNIVERSITY OF CINCINNATI COLLEGE OF MEDICINE, Eden and Bethesda Avenues. Organized in 1909 by the union of the Medical College of Ohio (founded in 1819) with the Miami Medical College (founded in 1852). The Medical College of Ohio became the Medical Department of the University of Cincinnati in 1896. Under a similar agreement, March 2, 1909, the Miami Medical College also merged with the University when the title of Ohio-Miami Medical College of the University of Cincinnati was taken. Present title assumed in 1915. Coeducational since organization. Candidates for admission to the freshman class must present three years of college preparation of not less than ninety hours. All candidates taking premedical work at the College of Liberal Arts, University of Cincinnati, must sign up for the seven-year combined course, and at the end of one year of satisfactory work in the College of Medicine the B.S. degree is granted by the College of Liberal Arts. The faculty consists of 112 professors, associate and assistant professors, 350 instructors and others, a total of 462. The course covers four years of eight months each, on the completion of which the M.B. degree is granted. A year's internship in an approved hospital is required, on completion of which the M.D. degree is granted. The fees are \$485 a year for legal residents of Cincinnati, plus laboratory fees; \$50 additional for those not legal residents of Cincinnati. The registration for 1938-1939 was 293; graduates, 71. The next session begins Sept. 22, 1939, and ends June 7, 1940. The Acting Dean is Stanley Dors, M.D.

Cleveland

WESTERN RESERVE UNIVERSITY SCHOOL OF MEDICINE, 2109 Adelbert Road.—Organized in 1843 as the Cleveland Medical College in cooperation with Western Reserve College. The first class graduated in 1844. It assumed the present title in 1881. In 1910 the Cleveland College of Physicians and Surgeons was merged. Coeducational since 1919. The faculty includes 88 professors and 231 lecturers, assistants and others, a total of 319. The curriculum covers three years of nine months each and one year of ten months. Three years of collegiate work are required for admission and a baccalaureate degree for graduation. The total fees are, respectively, \$442, \$430, \$415 and \$425. The registration for 1938-1939 was 266; graduates, 64. The next session begins Sept. 21, 1939, and ends June 12, 1940. The Dean is Torald Sollmann, M.D.

Columbus

OHIO STATE UNIVERSITY COLLEGE OF MEDICINE, Neil and Eleventh Avenues.—Organized in 1907 as the Starling-Ohio Medical College by the union of Starling Medical College (organized in 1847 by charter

MEDICAL EDUCATION

829

granted by the State Legislature changing the name from Willoughby Medical College, which was chartered March 3, 1834) with the Ohio Medical University (organized 1890). In 1914 it became an integral part of the Ohio State University with its present title. Coeducational since organization. The faculty consists of 66 professors, associate and assistant professors, 92 lecturers, instructors, demonstrators and others, a total of 158. Three years of collegiate work are required for admission. The course covers four years of thirty-four weeks each. Tuition fees are \$327 for the first year, \$231, \$231 and \$312 for each of the other three years for residents of Ohio, and \$150 additional for nonresidents. The registration for 1938-1939 was 306; graduates, 81. The next session begins Oct. 3, 1939, and ends June 10, 1940. The Dean is J. H. J. Upham, M.D.

OKLAHOMA
Oklahoma City

UNIVERSITY OF OKLAHOMA SCHOOL OF MEDICINE, 801 East Thirteenth Street.—Organized in 1900. Until 1910 gave only the first two years of the medical course in 1900. The first class graduated in 1911. Coeducational since organization. Since September, 1928, the entire four-year course has been given in Oklahoma City. It has a faculty of 27 professors, 26 associate professors, 20 assistant professors, 37 associates, 16 lecturers, 35 instructors, and 22 assistants, a total of 183. Three years of college work are required for admission. The B.S. in Medicine degree will not be conferred after June 3rd, 1940. The course covers four years of nine months each. Fees: \$50 "Maintenance and Incidental Fee" per semester, beginning with the freshman class of 1939-1940. Other annual course fees average \$128, \$95, \$53 and \$58, in the order given, beginning with the freshman year. For students not residents of Oklahoma there is a tuition charge of \$350 a year, plus laboratory and course fees as indicated for the different years. The registration for 1938-1939 was 226; graduates, 52. The next session begins September 18, 1939, and ends June 3, 1940. The Dean is Robert U. Patterson, M.D., C.M.

OREGON
Portland

UNIVERSITY OF OREGON MEDICAL SCHOOL, Marquam Hill.—Organized in 1887. The first class graduated in 1888, and a class graduated each subsequent year except 1898. The Willamette University Medical Department was merged in 1913. Coeducational since organization. It has a faculty of 91 professors and 164 lecturers, assistants and others, a total of 255. Entrance requirements are three years of collegiate work. The course covers four years of thirty-three weeks each. The total fees are, respectively, \$320, \$315, \$310 and \$316 for residents of Oregon, and \$60 a year additional for nonresidents. The registration for 1938-1939 was 253; graduates, 63. The next session begins Oct. 2, 1939, and ends June 7, 1940. The Dean is Richard B. Dillehunt, M.D.

PENNSYLVANIA
Philadelphia

HAHNEMANN MEDICAL COLLEGE AND HOSPITAL OF PHILADELPHIA, 35 North Fifteenth Street.—Organized in 1848 as the Homeopathic Medical College of Pennsylvania. In 1869 it united with The Hahnemann Medical College of Philadelphia, taking the latter title. Assumed present title in 1885. The first class graduated in 1849. Three years of collegiate work in a college of arts and sciences are required for admission. It has a faculty of 90 professors and 165 lecturers, instructors, and others, a total of 255. The work covers four years of eight months each. Fees are, respectively, \$515, \$512, \$512 and \$535. The registration for 1938-1939 was 553; graduates, 134. The next session begins Oct. 2, 1939, and ends June 6, 1940. The Dean is William A. Pearson, M.D.

JEFFERSON MEDICAL COLLEGE OF PHILADELPHIA, 1025 Walnut Street.—Organized in 1825 as the Medical Department of Jefferson College, Canonsburg, Pa. It was chartered with its present title in 1838. Classes have been graduated annually beginning 1826. In 1838 a separate university charter was granted without change of title, since which time it has continued under the direction of its own board of trustees. It has a faculty of 83 professors, associate and assistant professors and 192 associates, lecturers, demonstrators and instructors, a total of 275. Four years of college work and a bachelor's degree are required for admission. The course of study covers four years of eight and one-half months each. The total fees are, respectively, \$450, \$440, \$430 and \$430. The registration for 1938-1939 was 493; graduates, 112. The next session begins Sept. 20, 1939, and ends June 7, 1940. The Dean is Henry K. Mohler, M.D.

TEMPLE UNIVERSITY SCHOOL OF MEDICINE, 3400 North Broad Street.—Organized in 1901. The first class graduated in 1904. Coeducational since organization. The faculty numbers 33 professors and 196 associates, assistants and others, a total of 229. Three years of collegiate work are required for admission. The fees for each of the four years, respectively, are \$485, \$455, \$435 and \$455. The registration for 1938-1939 was 448; graduates, 117. The next session begins Sept. 20, 1939, and ends June 13, 1940. The Dean is William N. Parkinson, M.D.

UNIVERSITY OF PENNSYLVANIA SCHOOL OF MEDICINE, Thirty-Sixth and Pine Streets.—Organized in 1765. Classes were graduated in 1768 and in all subsequent years except 1772 and 1775-1779, inclusive. The original title was the Department of Medicine, College of Philadelphia. The present title was adopted in 1909. It granted the first medical diploma issued in America. In 1916 it took over the Medico-Chirurgical College of Philadelphia to develop it as a graduate school. Coeducational since 1914. The faculty consists of 115 professors, associate and assistant professors, and 380 lecturers, associates, instructors and others, a total

of 495. Three years of collegiate work are required for admission. The course covers four years of thirty-three weeks each. The tuition fee is \$500 each year, with a deposit fee of \$15, a general fee including student health of \$15 and a matriculation fee of \$5. The registration for 1938-1939 was 486; graduates, 122. The next session begins Sept. 25, 1939, and ends June 12, 1940. The Dean is William Pepper, M.D.

WOMAN'S MEDICAL COLLEGE OF PENNSYLVANIA, Henry Avenue and Abbottsford Road, East Falls.—Organized in 1850. Classes were graduated in 1852 and in all subsequent years except 1862. It has a faculty of 49 professors and 76 assistants, lecturers, and others, in all, 125. Three years of collegiate work are required for admission. The curriculum covers four years of eight and one-half months each. Total fees are, respectively, \$440, \$433, \$433 and \$455. The registration for 1938-1939 was 100; graduates, 21. The next session begins Sept. 20, 1939, and ends June 12, 1940. The Dean is Martha Tracy, M.D.

Pittsburgh

UNIVERSITY OF PITTSBURGH SCHOOL OF MEDICINE, Bigelow Boulevard.—Organized in 1886, as the Western Pennsylvania Medical College, and in 1908 became an integral part of the University of Pittsburgh, removing to the university campus in 1910. The first class graduated in 1887. Coeducational since 1899. The faculty is composed of 31 professors and 306 associates, assistants and others, a total of 337. Entrance requirements are two years of collegiate work. The course of study is four years of eight months each. The total fees are \$500 each year. The registration for 1938-1939 was 234; graduates, 51. The next session begins Sept. 18, 1939, and ends June 12, 1940. The Dean is W. S. McElroy, M.D.

SOUTH CAROLINA
Charleston

MEDICAL COLLEGE OF THE STATE OF SOUTH CAROLINA, 16 Lucas Street.—Organized in 1823 as the Medical College of South Carolina. The first class graduated in 1825. In 1832 a medical college bearing the present title was chartered and the two schools continued as separate institutions until they were merged in 1838. Classes were graduated in all years except 1862 to 1865, inclusive. In 1913, by legislative enactment, it became a state institution. Coeducational from 1895 to 1912, when privileges for women were withdrawn, being restored in 1917. It has a faculty of 46 professors and 45 associates, instructors and others, a total of 91. The course covers four years of eight months each. Three years of collegiate work are required for admission. The total fees are \$272 each year. Fees for nonresidents of the state, \$422 each year. The enrollment for 1938-1939 was 160; graduates, 43. The next session begins Sept. 28, 1939, and ends June 6, 1940. The Dean is Robert Wilson, M.D.

TENNESSEE
Memphis

UNIVERSITY OF TENNESSEE COLLEGE OF MEDICINE, 874 Union Avenue.—Organized in 1876 at Nashville as Nashville Medical College. First class graduated 1877, and a class graduated each subsequent year. Became Medical Department of University of Tennessee in 1879. In 1909 it united with the Medical Department of the University of Nashville to form the joint Medical Department of the Universities of Nashville and Tennessee. This union was dissolved in 1911. The trustees of the University of Tennessee College of Medicine by formal action of that board named the University of Tennessee College of Medicine as its legal successor. In 1911 it moved to Memphis, where it united with the College of Physicians and Surgeons. The Memphis Hospital Medical College was merged in 1913. Lincoln Memorial University Medical Department was merged in 1914. Coeducational since 1911. The faculty includes 104 professors and 144 assistants, instructors and others, a total of 248. Two years of collegiate work are required for admission. The B.S. degree in medicine is conferred at the end of the second year. The fees are \$120 quarterly. For residents of the state the charge is reduced \$50 each quarter. The registration for 1938-1939 was 425; graduates, 94. During the academic year of 1939-1940 the quarters begin July 7, Sept. 25, Dec. 29 and March 18, and end Sept. 23, Dec. 16, March 16 and June 8. The Dean is O. W. Hyman, Ph.D.

Nashville

MEHARRY MEDICAL COLLEGE, Eighteenth Avenue North and Heffernan Street. (For Negro Youth).—This school was organized in 1876 as the Meharry Medical Department of Central Tennessee College, which became Walden University in 1900. First class graduated in 1877. Obtained new chapter independent of Walden University in 1915. Coeducational since 1876. The faculty is made up of 46 professors and 30 instructors and lecturers, 76 in all. Two years' work in a college of liberal arts is required for admission. The curriculum covers four years of thirty-two weeks each. Tuition fees are, respectively, \$300, \$280, \$280 and \$290 each year. The registration for 1938-1939 was 183; graduates 30. The next session begins October 2, 1939, and ends May 31, 1940. The Dean is Edward L. Turner, M.D.

VANDERBILT UNIVERSITY SCHOOL OF MEDICINE, Twenty-First Street at Edgemoor.—This school was founded in 1874. The first class graduated in 1875. Coeducational since September 1925. The faculty numbers 230. For matriculation, students must be graduates of collegiate institutions of recognized standing or seniors in absentia, who will receive the bachelor degree from their college after having completed successfully at least one year of work in the school of medicine. The course covers four years of nearly nine months each. The total fees are, respectively, \$415, \$415, \$415 and \$420. The registration for 1938-1939 was 201; graduates, 49. The next session begins Sept. 25, 1939, and ends June 12, 1940. The Dean is Waller S. Leathers, M.D.

TEXAS

Dallas

BAYLOR UNIVERSITY COLLEGE OF MEDICINE, 810 College Avenue.—Organized in 1900 as the University of Dallas Medical Department. In 1903 it took its present name and became the Medical Department of Baylor University. It acquired the charter of Dallas Medical College in 1904. Coeducational since organization. The first class graduated in 1901. The faculty consists of 107 professors and 100 instructors and assistants, a total of 207. Entrance requirements are three years of collegiate work. The course covers four years of eight months each. The fees are, respectively, \$414, \$404, \$399 and \$424. The registration for 1938-1939 was 300; graduates, 70. The next session begins Oct. 2, 1939, and ends June 3, 1940. The Dean is W. H. Moursund, M.D.

Galveston

UNIVERSITY OF TEXAS SCHOOL OF MEDICINE, 912 Avenue B.—Organized in 1891. The first class graduated in 1892. Coeducational since organization. It has a faculty of 45 professors and 26 instructors and lecturers, a total of 71. The curriculum covers four years of eight months each. The entrance requirement is three years of collegiate work. The total fees are, respectively, \$88, \$92, \$100 and \$102. There is a matriculation fee of \$50 for each year. The registration for 1938-1939 was 377; graduates, 92. The next session begins Oct. 2, 1939, and ends May 31, 1940. The Dean is John W. Spies, M.D.

VERMONT

Burlington

UNIVERSITY OF VERMONT COLLEGE OF MEDICINE, Pearl Street, College Park.—Organized with complete course in 1822. Classes graduated in 1823 to 1836, inclusive, when the school was suspended. It was reorganized in 1853 and classes were graduated in 1854 and in all subsequent years. Coeducational since 1920. It has a faculty of 47 professors and 34 lecturers, instructors, preceptors and others, a total of 81. Three years of collegiate work are required for admission. The course of study covers four years of nine months each. For residents of Vermont the tuition fee is \$300 each session. Nonresidents are charged an additional \$150 each session. A \$25 fee is charged for the doctor's degree. The registration for 1938-1939 was 137; graduates, 38. The next session begins Sept. 13, 1939, and ends June 10, 1940. The Chairman of the Committee of Administration is E. H. Butties, M.D.

VIRGINIA

Charlottesville

UNIVERSITY OF VIRGINIA DEPARTMENT OF MEDICINE.—Organized in 1827. Classes were graduated in 1828 and in all subsequent years except 1865. Coeducational since the session of 1920-1921. It has a faculty of 44 professors and 37 lecturers, instructors, assistants and others, a total of 81. Three years of college work are required for admission. For residents of Virginia the total fees are, respectively, \$414, \$391, \$366 and \$361. Nonresidents are charged an additional \$50 each year. The registration for 1938-1939 was 246; graduates, 51. The next session begins Sept. 14, 1939, and ends June 10, 1940. The Dean is Harvey Ernest Jordan, Ph.D.

Richmond

MEDICAL COLLEGE OF VIRGINIA, Twelfth and Marshall Streets.—Organized in 1838 as the Medical Department of Hampden Sydney College. Present title was taken in 1854. In 1913 the University College of Medicine was merged. In 1914 the North Carolina Medical College was merged. Coeducational since 1918. Classes were graduated in 1839 and in all subsequent years. It has a faculty of 66 professors and 130 lecturers, instructors and others, a total of 196. Three years of collegiate work are required for admission. The course covers four years of eight and one-half months each. Total fees are, respectively, \$344, \$344, \$329 and \$361. Nonresidents are charged an additional \$125 each year. The registration for 1938-1939 was 297; graduates, 61. The next session begins Sept. 5, 1939, for the first year class; Sept. 18, 1939, for all other classes and ends June 4, 1940. The Dean is Lee E. Sutton Jr., M.D.

WISCONSIN

Madison

UNIVERSITY OF WISCONSIN MEDICAL SCHOOL, 408 North Charter Street.—Organized in 1907. Gave only the first two years of the medical course until 1925, when the clinical years were added. Coeducational since organization. Three years of collegiate work are required for admission. The B.S. degree in medical science is conferred at the end of the first year. It has a faculty of 64 professors and 67 lecturers, instructors and others, a total of 131. The fees are, respectively, \$212, \$192, \$165 and \$110. An additional fee of \$200 each year is charged nonresidents. The registration for 1938-1939 was 270; graduates, 52. The next session begins Sept. 20, 1939, and ends June 17, 1940. The Dean is William S. Middleton, M.D.

Milwaukee

MARQUETTE UNIVERSITY SCHOOL OF MEDICINE, 561 North Fifteenth Street.—Organized in December 1912, by the merger of the Milwaukee Medical College and the Wisconsin College of Physicians and Surgeons. Coeducational since organization. It has a faculty of 175. Three years of collegiate work are required for admission. The curriculum covers four years of eight and a half months each, and one year's internship in an approved hospital. The fees are as follows: first year, \$462; second year, \$462; third year, \$400; fourth year, \$400. The registration for 1938-1939 was 313; graduates, 69. The next session begins Sept. 25, 1939, and ends June 12, 1940. The Dean is Eben J. Carey, M.D.

CANADA

Alberta

UNIVERSITY OF ALBERTA FACULTY OF MEDICINE, Edmonton.—Organized in 1913. Coeducational since organization. Has given the complete six-year medical course since 1924. The faculty includes 23 full time and 45 part time professors, instructors, assistants and others, a total of 68. Tuition for the first year is \$150, for the second, third and fourth years, \$215; for the fifth and sixth years, \$225. The registration for 1938-1939 was 223; graduates, 32. The next session begins Sept. 26, 1939, and ends May 14, 1940. The Dean is Allan C. Rankin, M.D.

Manitoba

UNIVERSITY OF MANITOBA FACULTY OF MEDICINE, Mannafyne Avenue, Winnipeg. Organized in 1883 as Manitoba Medical College; first class graduated in 1886, and a class graduated each subsequent year. The college transferred all its property to the University of Manitoba in 1919 and assumed the present title. Coeducational since organization. The faculty includes 26 professors and 80 instructors and assistants, total of 106. Matriculation requirements include two years of collegiate work in the faculty of arts and science of a recognized university. The course extends over four years of eight months each and a hospital internship. The total fees are, respectively, \$296, \$291, \$301, \$301, \$80. The registration for 1938-1939 was 212; graduates, 56. The next session begins Sept. 22, 1939, and ends May 17, 1940. The Dean is A. T. Mathers, M.D.

Nova Scotia

DALHOUSIE UNIVERSITY FACULTY OF MEDICINE, Morris Street, Halifax.—Organized in 1867. Incorporated as the Halifax Medical College in 1875. Reorganized as an examining faculty, separate from the Halifax Medical College, in 1885. In 1911, in accordance with an agreement between the Governors of Dalhousie University and the Corporation of the Halifax Medical College, the work of the latter institution was discontinued and a full teaching faculty was established by the university. First class graduated in 1872. Coeducational since 1871. It has a faculty of 34 professors and 34 demonstrators, lecturers and others, a total of 68. Requires for matriculation two years of arts. The medical course covers four years and a hospital internship of one year. The fees are \$317, \$322, \$317, \$317 and \$307 for each year, respectively; \$250 additional registration fee payable by students outside the British Empire. The registration for 1938-1939 was 179; graduates, 37. The next session begins Sept. 12, 1939, and ends May 14, 1940. The Dean is H. G. Grant, M.D.

Ontario

QUEEN'S UNIVERSITY FACULTY OF MEDICINE, Kingston.—Organized 1854, first class graduated in 1855, and a class graduated each subsequent year. The faculty numbers 60. The fee for the first year is \$233, and \$255 for each of the other five years. The course covers six years of thirty teaching weeks each. The registration for 1938-1939 was 282; graduates, 43. The next session begins Sept. 28, 1939, and ends May 17, 1940. The Dean is Frederick Etherington, M.D.

UNIVERSITY OF WESTERN ONTARIO MEDICAL SCHOOL, Ottawa Avenue, London.—Organized in 1881 as the Western University Faculty of Medicine; first class graduated in 1883, and a class graduated each subsequent year. Present title in 1923. The medical school has been under the control of the Board of Governors of the University of Western Ontario since 1913. Coeducational since 1913. The faculty numbers 88. The course of study covers six years of eight months each. The total fees to residents of Canada for the last four years, respectively, are \$264, \$260, \$268 and \$268; nonresidents are charged \$488, \$484, \$492 and \$492 for each of the last four years. The registration for 1938-1939 was 212; graduates, 29. The next session begins Sept. 18, 1939, and ends May 18, 1940. The Dean is F. J. H. Campbell, M.D.

UNIVERSITY OF TORONTO FACULTY OF MEDICINE, Toronto.—Organized in 1843 as the Medical Faculty of King's College. Abolished in 1853. Reestablished in 1887. In 1902 it absorbed Victoria University Medical Department, and in 1903 it absorbed the Medical Faculty of Trinity University. Coeducational since 1903. The course of study covers six years of eight months each. The B.Sc. (Med.) degree is conferred at the end of the third or sixth year. It has a faculty of 74 professors and 353 lecturers, associates and others; a total of 427. The fees are \$226 for the first year; for the second, \$401; \$296 for the third year; \$321 for the fourth and fifth years, and \$353 for the sixth year. The registration for 1938-1939 was 798; graduates, 129. The next session begins Sept. 26, 1939, and ends May 18, 1940. The Dean is W. E. Gallie, M.D.

Quebec

LAVAL UNIVERSITY FACULTY OF MEDICINE, Quebec.—The Quebec School of Medicine, organized in 1848, became in 1852 the Laval University Faculty of Medicine; first class graduated in 1855, and a class graduated each subsequent year. The faculty numbers 81. The fees for each of the medical years are \$175 for residents of Canada. Nonresidents are charged an extra fee of \$175 each year. The premedical requirement is a B.A. degree or its equivalent. The registration for 1938-1939 was 299; graduates 32. The next session begins Sept. 20, 1939, and ends May 31, 1940. The Dean is P. C. Dagneau, M.D.

MCGILL UNIVERSITY FACULTY OF MEDICINE, 3640 University Street, Montreal.—Founded in 1823 as Montreal Medical Institution; became the Medical Faculty of McGill University in 1829; first class graduated under the university auspices in 1833. No session between 1836-1839, owing to political troubles. In 1905 it absorbed the Faculty of Medicine of the University of Bishop's College. Coeducational since 1919. Three years of collegiate work are required for admission. The length of the

MEDICAL EDUCATION

831

medical course is four years followed by one year of internship. The faculty consists of 58 professors and 154 lecturers and others, a total of 212. The total fees for each of the four medical years are \$391 plus \$100 for non-British subjects. The registration for 1938-1939 was 456; graduates, 99. The next session begins Sept. 6, 1939, and ends May 28, 1940. The Dean is A. Grant Fleming, M.D.

UNIVERSITY OF MONTREAL, FACULTY OF MEDICINE, 1265 St. Denis Street, Montreal.—Organized in 1843 as the Montreal School of Medicine and Surgery. In 1891, by Act of Parliament, the Medical Faculty of

Laval University (organized in 1878) was absorbed. Present name by Act of Parliament in 1920. A class was graduated in 1843 and each subsequent year. Coeducational since 1925. The faculty numbers 133. The B.A. or B.S. degree, or its equivalent, is a prerequisite to the pre-medical year, which precedes a five year medical course. The total fees for each of the five years respectively are \$243, \$227, \$262, \$240 and \$218. The registration for 1938-1939 was 205; graduates, 29. The next session begins Sept. 18, 1939, and ends June 15, 1940. The Dean is Albert LeSage, M.D.

DESCRIPTION OF SCHOOLS OF THE BASIC MEDICAL SCIENCES

ALABAMA

University (Tuscaloosa)

UNIVERSITY OF ALABAMA SCHOOL OF MEDICINE.—Organized in 1859 at Mobile as the Medical College of Alabama. Classes graduated in 1861 and subsequent years excepting 1862 to 1868, inclusive. Reorganized in 1897 as the medical department of the University of Alabama. Present title assumed in 1907, when all property was transferred to the University school was removed to the university campus near Tuscaloosa. Coeducational since 1920. The faculty includes 15 professors and 12 instructors, assistants, and others, a total of 27. The tuition fees are \$271 each year. Each class is limited to fifty students. The registration for 1938-1939 was 101. The next session begins Sept. 13, 1939, and ends May 28, 1940. The Dean is Stuart Graves, M.D.

MISSISSIPPI

University

UNIVERSITY OF MISSISSIPPI SCHOOL OF MEDICINE.—Organized in 1903. Coeducational since organization. Gives only the first two years of the medical course. A clinical department was established at Vicksburg in 1908 but was discontinued in 1910 after graduating one class. The session extends over eight and one-half months. Entrance requirements are three years of collegiate work. The B.S. degree in medicine is conferred at the end of the second year. The faculty includes 8 professors, 2 assistant professors, 1 associate professor, 2 adjunct professors, 16 instructors, assistants and others, a total of 29. The total fees for the first year are \$353, and for the second year \$325. The nonresident fee is \$50 additional each year. The registration for 1938-1939 was 41. The next session begins Sept. 20, 1939, and ends June 3, 1940. The Dean is B. S. Guyton, M.D.

MISSOURI

Columbia

UNIVERSITY OF MISSOURI SCHOOL OF MEDICINE.—Organized at St. Louis in 1845; was discontinued in 1855 but was reorganized at Columbia in 1872. Teaching of the clinical years was suspended in 1909. Coeducational since 1872. The faculty includes 19 professors and 16 instructors, lecturers and others, a total of 35. The entrance requirements are 90 semester hours of collegiate work. The B.S. degree in medicine is conferred at the end of the second year. Total fees for the first year are \$191, for the second, \$170. Nonresidents of the state are not admitted. The registration for 1938-1939 was 72. The next session begins Sept. 11, 1939, and ends June 4, 1940. The Dean is Dudley S. Conley, M.D.

NEW HAMPSHIRE

Hanover

DARTMOUTH MEDICAL SCHOOL.—Organized by Dr. Nathan Smith in 1797. The first class graduated in 1798. It is under the control of the trustees of Dartmouth College. Courses of the third and fourth year were discontinued in 1914. The faculty consists of 17 professors and 13 instructors, a total of 30. Three years of collegiate work and candidacy for the bachelor's degree are required for admission. The course covers nine calendar months in each year, or eight months of actual teaching. Candidates for the A.B. degree in Dartmouth College may substitute the work of the first year in medicine for that of the senior year in the academic department. The tuition is \$450 for each year. The registration for 1938-1939 was 40. The next session begins Sept. 21, 1939, and ends June 14, 1940. The Dean is John P. Bowler, M.D.

NORTH CAROLINA

Chapel Hill

UNIVERSITY OF NORTH CAROLINA SCHOOL OF MEDICINE.—Organized in 1890. Until 1902 this school gave only the work of the first two years, when the course was extended to four years by the establishment of a department at Raleigh. The first class graduated in 1903. A class was graduated each subsequent year, including 1910, when the clinical department at Raleigh was discontinued. Coeducational since 1914. Three years of collegiate work are required for admission. The B.S. degree in medicine is conferred at the end of the first year. The fees for each year are \$295 for residents; nonresidents, an additional fee of \$100. The registration for 1938-1939 was 64. The next session begins Sept. 14, 1939, and ends June 11, 1940. The Dean is Wm. deB. MacNider, M.D.

Wake Forest

WAKE FOREST COLLEGE SCHOOL OF MEDICAL SCIENCES.—Organized in 1902. The faculty numbers 11 professors, 2 assistant professors, 9 instructors, and 1 visiting lecturer, making a total of 23. Coeducational since 1927. The name was changed from the School of Medicine to the School of Medical Sciences in 1937, in view of the fact that it offers only the first two years of the medical course, which is made up largely of the medical sciences. Ninety semester hours of collegiate work are required for admission. The B.S. degree is given after the completion of the first year in the School of Medical Sciences, to those who do not already have that degree. Each annual course extends over nine months. The fees for each year are \$300. The registration for 1938-1939 was 5. The next session begins Sept. 14, 1939, and ends May 27, 1940. The Dean is C. C. Carpenter, M.D.

NORTH DAKOTA

Grand Forks

UNIVERSITY OF NORTH DAKOTA SCHOOL OF MEDICINE.—Organized in 1905. Offers only the first two years of the medical course. Coeducational since organization. Three years' work in a college of liberal arts is required for admission. The B.S. degree in combined arts-medical course is conferred at the end of the second year. The faculty consists of 8 professors and 8 instructors, a total of 16. The fees are \$80 each year for resident students and \$165 for nonresidents. The registration for 1938-1939 was 48. The next session begins Sept. 19, 1939, and ends June 11, 1940. The Dean is H. E. French, M.D.

SOUTH DAKOTA

Vermillion

UNIVERSITY OF SOUTH DAKOTA SCHOOL OF MEDICAL SCIENCES.—Organized in 1907 as the University of South Dakota School of Medicine. Present title in 1938. Coeducational since organization. Offers only the first two years of the medical course. Three years' work in a college of liberal arts is required for admission. Students who complete the third year of premedical work in the College of Arts and Sciences at the University of South Dakota may apply the work of the first year of medicine to the A.B. degree. The B.S. degree is conferred at the end of the second year on those students who do not hold a previous Bachelor's degree. The faculty numbers 18. The tuition is \$150 each year for residents and \$250 for nonresidents. The registration for 1938-1939 was 42. The next session begins Sept. 20, 1939, and ends June 10, 1940. The Dean is Joseph C. Ohlmacher, M.D.

UTAH

Salt Lake City

UNIVERSITY OF UTAH SCHOOL OF MEDICINE, University Street.—Organized in 1906. Coeducational since organization. Gives only first two years of medical course. Each school year covers thirty-six weeks. Three years of collegiate work are required for admission. The medical faculty consists of 10 professors, 1 instructor, 20 lecturers and demonstrators, and 5 fellows, assistants, and technicians, a total of 36. The fees for each year are \$229. There is a nonresident fee of \$25 for each quarter. The registration for 1938-1939 was 59. The next session begins Sept. 25, 1939, and ends June 1, 1940. The Dean is L. L. Daines, M.D.

WEST VIRGINIA

Morgantown

WEST VIRGINIA UNIVERSITY SCHOOL OF MEDICINE.—Organized in 1902, gives the first two years of the medical course. Coeducational since organization. Three years of collegiate work are required for admission. The B. S. degree in medicine is conferred at the end of the second year. Session extends through nine months. Faculty numbers 24. Fees for residents of the state, \$254; nonresidents, \$404, each year. The registration for 1938-1939 was 51. The next session begins Sept. 19, 1939, and ends June 8, 1940. The Dean is Edward J. Van Lier, M.D.

CANADA

Saskatchewan

UNIVERSITY OF SASKATCHEWAN SCHOOL OF MEDICAL SCIENCES, Saskatoon.—Organized in 1926. Coeducational. Offers the first two years of the medical course. Students require three more years of medicine for graduation. Two years of collegiate work are required for admission. The B.A. degree is conferred at the end of the second year. The medical faculty includes 7 professors and 3 lecturers and assistants, a total of 10. The fees are \$150 for each year. The registration for 1938-1939 was 47. The next session begins Sept. 25, 1939, and ends May 10, 1940. The Dean is W. S. Lindsay, M.B.

HOSPITALS APPROVED FOR TRAINING INTERNS

The following general hospitals are considered in position to furnish acceptable internships of at least one year duration. They are also accredited for mixed residencies, which represent general assignments following an approved intern service. The + sign indicates additional approval for residencies in specialties.

HOSPITALS, 734. INTERNSHIPS, 7,832 Capacity, 234,618 Beds

The terms used in the column "Type of Internship" are defined as follows:

1. A full rotating internship provides training in medicine, surgery, pediatrics, obstetrics and the laboratories. (X-ray and laboratory duties may be combined with clinical services or constitute separate assignments.)

2. A mixed or limited rotating internship covers more than one of

the clinical specialties but does not include all of the divisions listed above.

3. A straight internship is an assignment limited to a single department but may include the subspecialties of the same branch. Straight internships are now approved in the divisions of medicine, surgery, pediatrics and pathology.

HOSPITALS APPROVED FOR INTERNSHIPS IN THE DOMINION OF CANADA

For the benefit of graduates of approved medical colleges who desire an internship in Canada, the Council on Medical Education and Hospitals of the American Medical Association has declared that hospitals which conform to the standards of the Department of Hospital Service of the Canadian Medical Association should be regarded as giving an internship equivalent in educational value to that offered by hospitals in the United States approved for intern training by the Council. It is understood, however, that this statement applies only to hospitals that are unofficially "Approved" under the Canadian plan and does not apply to that group referred to as "Recommended."

The following list of hospitals, revised to June 1939, has been furnished by the Department of Hospital Service.

Name of Hospital	Location	Name of Hospital	Location	Name of Hospital	Location
Victoria General Hospital.....	Halifax, N. S.	McKellar General Hospital....	Fort William, Ont.	Metropolitan General Hosp....	Windsor, Ont.
St. John General Hospital.....	St. John, N. B.		at	Hotel Dieu of St. Joseph Hosp.	Windsor, Ont.
Hospital du St. Sacrement.....	Quebec, Que.		at	Children's Hospital.....	Winnipeg, Man.
Hotel Dieu de Quebec.....	Quebec, Que.			Misericordia Hospital.....	Winnipeg, Man.
Hospital of the Infant Jesus.....	Quebec, Que.	Ottawa General Hospital.....	Ottawa, Ont.		
Jeffrey Hale's Hospital.....	Quebec, Que.	Kingston General Hospital....	Kingston, Ont.		
Children's Memorial Hosp.....	Montreal, Que.	Hospital for Sick Children....	Toronto, Ont.		
Hospital Notre Dame.....	Montreal, Que.	Mount Sinai Hospital.....	Toronto, Ont.		
Hospital Ste. Justine.....	Montreal, Que.	St. Joseph's Hospital.....	Toronto, Ont.		
Hotel Dieu of St. Joseph.....	Montreal, Que.	St. Michael's Hospital.....	Toronto, Ont.		
Hospital Ste. Luc.....	Montreal, Que.	Toronto East General Hosp....	Toronto, Ont.		
Jewish General Hospital.....	Montreal, Que.	Toronto General Hospital....	Toronto, Ont.		
Montreal General Hospital....	Montreal, Que.	Toronto Western Hospital....	Toronto, Ont.		
Royal Victoria Hospital.....	Montreal, Que.	Women's College Hospital....	Toronto, Ont.	St. Paul's I	B. C.
St. Mary's Hospital.....	Montreal, Que.	Brantford General Hospital....	Brantford, Ont.	Vancouver	C.
Woman's General Hospital,	Montreal, Que.	St. Joseph's Hospital.....	London, Ont.	Royal Jubil	C.
(Westmount).....	Montreal, Que.	Victoria Hospital.....	London, Ont.	St. Joseph's Hospital.....	Victoria, B. C.

NOTES

* Majority of patients available for teaching purposes.

† Straight Internships following previous intern training are included in residency list. Total house staff, 200.

- (a) In lieu of maintenance.
- (b) Salary established by government pay tables.
- (c) \$30 per month second year.
- (d) January, July, October.
- (e) Bonus of \$50.
- (f) Bonus of \$25.
- (g) Bonus of \$100.
- (h) Jan., March, July, September, November.
- (i) Bonus of \$120.
- (j) Bonus of \$100.
- (k) March, July, November.
- (m) January, July, September.

- (n) Quarterly.
- (o) January, April, September.
- (p) Bonus of \$50.
- (q) Every two months.
- (r) April, July, October.
- (s) Bonus of \$300.
- (t) Bonus of \$150.
- (u) Bonus of \$75.
- (v) January, April, July, August.
- (w) January, May, September.
- (x) July, September, October.
- (y) Every six weeks.
- (z) Bonus of \$180.
- (aa) \$10 per month second year.
- (bb) \$25 per month first year; \$50 per month second year; bonus of \$100.

- 124. Kaulkeolani Children's Hospital, Honolulu.

APPROVED RESIDENCIES AND FELLOWSHIPS

Hospitals, 518; Residencies, 3,951; Fellowships, 611

The following institutions approved by the Council on Medical Education and Hospitals are considered in position to furnish acceptable training in various specialties as indicated below. Residencies in specialties, as defined by the Council, are straight services of one or more years following an approved internship. A fellowship is a form of apprenticeship which in some cases is indistinguishable from a residency, although it usually offers greater opportunity for the study of basic sciences and research. Ordinarily a fellowship is a university rather than a hospital appointment. Mixed residencies are general hospital assignments following internship. (They include services classified as general residencies and chief residencies.)

The star (*) indicates hospitals that are also approved for the training of interns. All hospitals on the approved intern list are likewise accredited for general or mixed residencies.

Mayo Foundation Fellowships—The Mayo Foundation for Medical Education and Research, Rochester, Minnesota; D. C. Balfour, director; three-year fellowships, beginning quarterly, leading to the degree of M.S. or Ph.D. with field named from the University of Minnesota: in Anesthesia, Dermatology and Syphilology, Internal Medicine, Neurology and Psychiatry, Neurosurgery, Obstetrics and Gynecology, Ophthalmology, Orthopedic Surgery, Otolaryngology, Pathology, Pediatrics, Physical Medicine, Plastic Surgery, Proctology, Radiology, Surgery, Urology; stipend \$900 per year (clinical fellowships including pathology and radiology—278).

- Compensation arranged by medical school and hospital.
- Represents number of patients treated.
- In lieu of maintenance.
- Outpatient and home delivery service only.
- Total represents both neurologic and psychiatric outpatient visits.
- Includes both ophthalmologic and otolaryngologic patients.
- Includes residents, assistant residencies and straight internships following previous intern training.
- Hospital facilities by affiliation.
 - Inpatients: Numbers refer to total inpatients treated in specialty. Obstetrical admissions do not include newborns. In pathology and anesthesiology total hospital admissions are used.
 - The percentage of free patients refers to the entire hospital service.
 - Deaths and autopsies are reported for individual specialties. In obstetrics only maternal deaths are included; in anesthesiology, pathology and radiology all hospital deaths are listed exclusive of stillbirths.
 - Hospital service confined to drug addicts.
 - Applications will be considered only from men who have had a previous year's training in some recognized pathological laboratory.
 - Includes gynecology.
 - Includes neurology.
 - Hospital appoints residents from own house staff.
 - Includes neurosurgery.
 - Includes orthopedics.

- Separate appointments approved in roentgenology and radium therapy.
- Orthopedic resident covers eye, ear, nose and throat service.
- Apply to chief of service for information about affiliating hospitals.
- Three assistant residents serve six months in obstetrics.
- Service transferred to Welfare Hospital.
- Includes obstetrics.
- Several services include obstetrics-gynecology.
- Includes proctology.
- Admissions confined to children.
- Includes dermatology.
- Affiliating—usually with New York Post-Graduate Medical School, New York City.
- Includes thoracic surgery.
- Private and semi-private pavilions.
- Dental as well as medical degree required.
- Includes x-ray and radium therapy.
- Mixed residencies represent general hospital experience of at least one year duration following an approved internship. All hospitals approved for intern training are also certified for general or mixed residencies.
- Includes three research residencies at the Research Division for Chronic Diseases, New York City.

SATURDAY, AUGUST 26, 1939

ADVANCES IN MEDICAL EDUCATION

During the past five years, in spite of financial difficulties, the survey of medical schools conducted by the Council on Medical Education and Hospitals has yielded tangible results in organization, equipment and resources of medical schools. This is true to a degree of all, but most significant in those institutions which, when visited, showed the greatest need. Among these lower ranking schools, twenty-four have increased their budgets by more than a million dollars, the average amount per school being \$47,000. Twenty-five have increased the number of salaried instructors. Twenty-two have definitely improved their procedure in the selection of students and have adopted higher scholastic standards for admission. For better preclinical facilities, seventeen schools have expended from \$29,000 to \$500,000 each. In twenty schools the cost of improved facilities for clinical teaching aggregates \$10,000,000. While money alone does not guarantee a sound educational institution, adequate financial support is absolutely essential for a medical school which would meet the exacting standards of the present day. The number of schools which can meet these standards is steadily increasing.

The prevailing situation is a happy contrast to the disorderly conditions which confronted the Council during the first five years of its existence—from 1904 to 1909. At that time many of the so-called medical schools were proprietary and their existence depended largely on student fees. Their faculties were without special training in the subjects they taught and had neither the facilities nor the time for research. Teaching was didactic with the meager laboratory and clinical facilities available at the time.

Finally, the most important element in medical education, the student and his qualifications, are in sharp contrast to the average student of thirty years ago. From 1904 to 1909 only the better medical schools required that entering students be graduates of high

schools. Today, while the statutes of five states still require but one year or less of preliminary preparation before entering medical school, 96.2 per cent of the last entering class of medical students had had three years or more of premedical education.

The activities of the Council in undergraduate medical education over the past thirty-five years have yielded incalculable benefits to the public health.

**TERMINOLOGY IN GRADUATE
MEDICAL EDUCATION**

Unfortunately, a lack of uniformity prevails in the use of such terms as graduate medical education, post-graduate medical instruction and continuation study. Various organizations have attempted to formulate definitions applicable to the specific circumstances with which they were concerned. Since 1937 the Council on Medical Education and Hospitals has been engaged in a study of graduate medical education particularly as it applies to courses for practicing physicians. To facilitate this survey, an attempt is being made to formulate suitable terminology which may be acceptable to those interested.

Graduate medical education in the broad sense covers all types of instruction which follow the award of the M.D. degree. In a more restricted sense, however, the term applies to well organized, systematic, scientific and clinical instruction planned for the benefit of the student under the supervision of a medical school, hospital or other educational institution. It may or may not lead to other academic degrees. Graduate education includes apprenticeships in the form of residencies and fellowships as well as other opportunities for graduate study with less dependence on clinical experience. The term residency is applied to a hospital service of one or more years' duration, limited to a single field and following an approved internship. Fellowships in some cases are indistinguishable from residencies; in others they offer greater opportunity for the study of basic sciences and research. Fellowships are more often university than hospital appointments and may be under the direction of the graduate school. This type of instruction is ordinarily designed to prepare the physician for practice of a specialty and is usually a requirement of the specialty boards.

The term "postgraduate" has been applied to short periods of study undertaken by the physician after licensure and after he has established himself in practice. Because abuses of the diploma privilege have given to this word an unsavory connotation, it may well be discarded. Currently two general forms of continuation study are offered. The first consists of courses offered in metropolitan centers with facilities for systematic instruction as provided in medical and other

educational institutions where abundant clinical material and medical laboratories are available; these may be designated "opportunities for continuation study with ample facilities for clinical instruction." The second form of postgraduate study now being offered practicing physicians is by lectures, demonstrations and clinics. This differs in that the programs may be more brief and are made available to the physician in or close to his home and therefore do not cause any serious interruption of his practice. The extension divisions of universities have aided materially in organizing such courses in cooperation with state medical societies, since the technic of instruction follows the somewhat conventional pattern of extension courses in nonmedical subjects. In general it may be said that physicians engaging in continuation study desire two kinds of courses: (1) instruction in subjects which were incompletely or unsatisfactorily taught during their undergraduate period and (2) subjects of practical value such as recent advances in the prevention, diagnosis and treatment of disease.

Regardless of the terms applied to the particular forms of graduate study, the educational program should be systematic in organization and, above all, clinical and scientific in content. Finally, the success of the present ventures in this field depend, first, on the willingness and ability of medical educators to provide facilities and facilities in medical centers and hospitals and, second, on the development of incentives for practicing physicians, so that they may be encouraged to continue their medical studies on a voluntary basis.

CONFERENCES ON THERAPY

Actual reports of conferences by members of the departments of pharmacology and medicine of Cornell University Medical College and the New York Hospital, in collaboration with other departments, have appeared in *THE JOURNAL* since December 1938.¹ Many pharmacologists and members of other departments of medical schools as well as practicing physicians have expressed their belief that these conferences on therapy are most helpful for a proper understanding of pharmacology and for its integration in the medical curriculum. There is practically no liaison of phar-

macology with other clinical departments in the medical school with the exception of medicine. It is desirable for all clinical departments to promote a better understanding of such essential subjects as toxicology and biologic, chemical and clinical assays.

Evaluation of the use of drugs in the preventive diagnosis and treatment of disease is difficult and the application of therapeutic measures is an individual matter requiring judgment of clinical circumstances. Clinically trained instructors are better equipped to teach therapeutics than are others without such training. The recent development of the conference on therapy brings together those whose interest begins with the initial development of an agent proposed for therapeutic use and those concerned with its final utilization in the prevention, diagnosis and treatment of disease. Pharmacology, being a pure science, is somewhat aloof from clinical medicine, and teachers of pharmacology are frequently quite detached from the patient. Teachers should, and in many cases do, realize that students are interested in pharmacology because they are anxious to become familiar with the biologic action of drugs. Their ultimate goal is the application of this knowledge in the practice of medicine.

Other schools of medicine have introduced conferences on therapy in a manner somewhat different from that tried at Cornell. Some utilize case records which are presented in therapeutic discussions revolving around the problems presented by the individual patient. At other schools therapeutic conferences are held at the bedside. Sometimes discussions by pharmacologists and the preclinical teachers throw light on the methods of treatment, which are carried out in the presence of students. Some instructors contend that conferences on therapy should include members of the departments of radiology, surgery, pediatrics and other specialties of medicine, so that the therapeutic aids of these departments, including physical agents, may be brought to the attention of students. Much of the success of conferences of this kind depends on the desire for cooperation on the part of other departments in the medical school as well as on the method by which they are conducted.

Informal instruction in the use of therapeutic agents by pharmacologists and others competent to judge therapeutic activity should lead to a better understanding by medical students and practicing physicians of the usefulness or uselessness of many of the therapeutic agents now being proposed. It would also serve to augment the work of the Council on Pharmacy and Chemistry. Such conferences provide excellent opportunities to point out the fallacies of both therapeutic faddism and nihilism and give physicians a more critical attitude toward all drugs. By suitable development of this technic in medical education, pharmacology may find its rightful place in the curriculum.

Current Comment

WHAT'S A DOCTOR WORTH?

Recent issues of Philadelphia newspapers published the prevailing wage rates adopted by the Philadelphia County Assistance Board for occupations of various types. The highest rate given appears to be that for a bricklayer who is a skilled foreman. To him the sum of \$1.79 an hour is permitted. Next comes an iron and steel worker, who gets \$1.65 an hour, and after that an ordinary bricklayer, who gets \$1.62 an hour. There are still some occupations which are preferable to that of physician, including that of marble setter and polisher at \$1.60 an hour and plasterer at \$1.55 an hour. In the next group come the doctors. Among those who are allowed \$1.51 an hour are found the air compressor operator, the dredge operator, the power shovel operator, the pump operator, the roller operator, the architect (registered or certified), the statistician (graduate or certified), the lawyer and the physician. There must be some explanation for this classification but it is not easily apparent. The study of such lists provides much interesting information. For example, a tree pruner, who might be considered in the professional class, gets only \$0.59 an hour; a sign painter, whose work is in the nature of artistry, \$1.29 an hour; a secretary-stenographer, \$0.70 an hour, and a translator \$1 an hour. The lowest rate paid to anybody is \$0.50 an hour. A machinist's helper gets \$0.59 an hour but a marble setter's helper gets \$1 an hour and a riprapper gets \$0.59 an hour. A concrete spreader gets \$0.59 an hour and an asphalt spreader gets \$0.65 an hour. Evidently it depends on what you are spreading around.

ALLERGIC IRRITABILITY IN RHEUMATIC AND NEPHRITIC PATIENTS

Some experimental evidence indicates that focal infections, especially with hemolytic streptococci, may alter nonspecific allergic reactivity. Because of the possible role of focal infection in both rheumatic fever and acute hemorrhagic nephritis, Schultz¹ has investigated the nonspecific cutaneous reactivity of patients with these diseases to such simple foreign proteins as rabbit serum and has compared this reactivity with the response of these patients to streptococcus nucleoprotein and tuberculin. On a given day the following materials were injected intracutaneously in different areas on the volar surface of the forearms, the respective test dose indicated being diluted to 0.1 cc. with physiologic solution of sodium chloride:

1. Hemolytic streptococcus nucleoprotein (strain Q33) 0.001 mg., prepared by the method described by Lancefield.
2. Human tuberculin (O. T.) 0.05 mg.
3. Normal rabbit serum 0.05 cc.

The reactions to nucleoprotein and tuberculin were recorded after twenty-four and forty-eight hours. There was no correlation apparent between the presence of carditis or arthritis, the degree of fever or the age of the patient and the development of secondary reactions to rabbit serum. In nephritis it is impossible with the

data obtained to dissociate the two factors of focal infection and the stage of the disease, for all patients in the acute hemorrhagic stage who were tested had also suffered recent focal infections. It was concluded, however, that increased allergic irritability, as demonstrated by the development of secondary reactions following the intracutaneous injection of small amounts of rabbit serum, occurred more frequently in patients with rheumatic fever or Bright's disease than in controls. Furthermore, the incidence of this increased allergic irritability was greater in individuals who had had recent focal infections. Correlation between the presence of hypersensitivity to hemolytic streptococcus nucleoprotein or tuberculin and increased allergic irritability could be established only to the extent that secondary reactions to rabbit serum were not observed among those who had not recently experienced a focal infection in the absence of hypersensitivity to both nucleoprotein and tuberculin. Further evidence is thus provided, Schultz believes, that alterations in tissue reactivity are associated with both the rheumatic and the nephritic states.

THE VITAMIN B COMPLEX UNFOLDS

With increasing knowledge regarding the chemistry of the constituents of the vitamin B complex, the isolation and characterization of still other components is facilitated. The list of indispensable dietary factors included in the vitamin B group has been enumerated by Nelson.¹ It is still uncertain whether all of these are specific entities, but several have been isolated in crystalline form and a few have been synthesized. It is known that man requires thiamin and nicotinic acid, and recently evidence has been secured² that riboflavin is indispensable in human nutrition. The rat does not require nicotinic acid³ but develops a characteristic dermatitis in the absence of vitamin B₆, which is known as the rat acrodynia factor. The latter material has been obtained in crystalline form and also has been synthesized, and a recent report⁴ indicates that it, like nicotinic acid, possesses a structural relationship to pyridine. The chick develops a dermatosis when restricted to a heated ration or when the so-called filtrate factor or antidermatosis factor is absent. This condition does not improve when nicotinic acid is added to the feed. Wooley and his co-workers⁵ have shown that this filtrate factor (part of the vitamin B complex) is chemically similar to pantothenic acid, a compound widely distributed in natural foods and consisting of an unidentified hydroxyacid and β -alanine.⁶ The demonstration by Jukes⁷ that the calcium salt of pantothenic acid is highly effective in curing chick dermatosis would seem to bring the identification of still another part of the water soluble B group of vitamins to the verge of completion, awaiting only the final determination of the structure of pantothenic acid.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Changes in Health Officers.—Dr. David B. Snelling, Tusculumbia, formerly assistant to the health officer of Colbert County, has been appointed health officer of Choctaw County. He succeeds Dr. Herbert A. McClure, Butler, who took over a similar position in Lamar County.

Regional Meeting.—The Northwestern Division of the Alabama State Medical Association will meet in Tusculumbia September 14, with the following speakers, among others: Drs. Chalmers H. Moore, Birmingham, "Diagnosis of Brain Tumors"; Thomas J. Payne Jr., Jasper, "Indications, Preparation and Administration of Blood Transfusions," and Raymond R. Callaway, Birmingham, "Infections of the Kidney."

CALIFORNIA

Society News.—At a meeting of the section on medicine and pediatrics of the San Francisco County Medical Society, August 1, Dr. Ernest G. Lion discussed "Types of Insomnia and Their Treatment." The section on surgery was addressed August 15 by Drs. Nelson J. Howard on "Hormonal Influence on the Normal and Abnormal Breast"; Leo Eloesser, "Results of Treatment of Carcinoma of the Breast by Preoperative Radiation and Operation," and Leo H. Garland, "Use of Radiation Therapy in Carcinoma of the Breast." At a meeting August 29 the section on urology will be addressed by Drs. Charles P. Mathe on persistent cystitis associated with vesical fistulas and osteomyelitis of the pelvis and Edward A. Levin, "Dermatologic Lesions of the Male Genitalia."—A recent meeting of the Kern County Medical Society was addressed in Bakersfield by Dr. William T. Grant, Los Angeles, on "Surgical Treatment of Epilepsy."

COLORADO

Dr. Webb Awarded Trudeau Medal.—Dr. Gerald B. Webb, Colorado Springs, research director, Colorado Foundation for Research in Tuberculosis, received the Trudeau Medal of the National Tuberculosis Association during the annual meeting in Boston June 26-29. The award was made in recognition of Dr. Webb's attempts "to produce specific immunity against tuberculosis by the inoculation of animals with very minute numbers of tubercle bacilli." Dr. Webb received his degree in medicine from the Denver College of Medicine in 1896. He is consultant to the Methodist, Sunnyside and Glickner sanatoriums and chief of staff at the Union Printers Home. He was president of the National Tuberculosis Association in 1920 and of the American Clinical and Climatological Association, 1929-1930, and has been delegate to several international congresses on tuberculosis. During the World War he was senior tuberculosis consultant with the American Expeditionary Forces.

GEORGIA

Changes in Health Officers.—Dr. Paul M. Golley, Chapel Hill, N. C., has been chosen health commissioner of Walker and Catoosa counties succeeding Dr. Richard C. Shepard, who resigned to enter private practice in Lafayette.—Dr. Stuart P. Vandiviere, Franklin, N. C., has been placed in charge of the Baldwin County health department.

Chattahoochee Valley Medical Meeting.—Dr. Marye Y. Dabney, Birmingham, Ala., was chosen president of the Chattahoochee Valley Medical Association at its thirty-ninth annual session at Radium Springs, Albany, July 11-13. Among the speakers on the program were:

Dr. William G. Harrison Jr., Birmingham, Relationship of the Physiology of Heart Failure to Treatment.
Dr. Lincoln Sydnor Lafitte, Jacksonville, Fla., Quinidine in Some Manifestations of Heart Diseases.
Dr. Joseph H. Boland, Atlanta, Some Orthopedic Aspects of Chronic Arthritis.
Dr. James R. Garber, Birmingham, The Obstetrical Significance of the New Born at Birth.
Dr. Thomas E. Buckman, Jacksonville, Macrocytic Anemia in Early Life.
Dr. James M. Mason, Birmingham, Cirroid Aneurysm of the Scalp.
Dr. Mercer S. Davie, Dothan, president, Medical Association of the State of Alabama, delivered the W. J. Love Memorial Address on "American Medicine."

ILLINOIS

Mortality Trends in Illinois Since 1925.—The state department of health has issued a study of mortality trends from 1925 to 1939. The general death rate for 1925 was 11.5 per thousand of population and for 1938 it was 10.7. Infant mortality has steadily declined: in 1927 it was 64 per thousand live births and in 1938 it was 41. Deaths of mothers declined from 5.5 per thousand births in 1925 to 3.1 in 1938. Heart disease, cancer and diabetes have increased, but there are more persons in the population of an age to suffer these diseases. The rates from heart disease in 1925 and in 1938 were 186.9 and 313.5 per hundred thousand, respectively. Most of the increase occurred among persons of the higher age levels. Deaths from cancer rose, a rate of 102.2 per hundred thousand in 1925 to a rate of 136.4 in 1938. Diabetes increased from 19.7 to 27.6 per hundred thousand of population.

Chicago

Capps Prize Announcement.—The Institute of Medicine of Chicago offers again the Joseph A. Capps Prize of \$400 for the most meritorious investigation in medicine or in the specialties of medicine. Competition is open to graduates of medical schools in Chicago who have completed an internship or a year of laboratory work in 1937 or thereafter. The investigation may also be in the fundamental sciences provided the work has a definite bearing on a medical problem. Manuscripts must be submitted to the secretary of the institute, 86 East Randolph Street, Chicago, not later than December 31.

Course in Hospital Administration.—A survey course for persons actively engaged in the administration of hospitals will be offered evenings at University College, University of Chicago, during the autumn and winter, in cooperation with the American College of Hospital Administrators. Among the lecturers will be: Drs. Robin C. Buerki, president of the college of hospital administrators; Bert W. Caldwell, executive secretary, American Hospital Association; Malcolm T. MacEachern, associate director, American College of Surgeons, and Herman Smith, medical superintendent of Michael Reese Hospital.

INDIANA

Personal.—Dr. George W. Bowman, Indianapolis, has been appointed state director for venereal disease control in the state health department, according to the Indianapolis Star August 5. He succeeds Dr. Wendell C. Kelly, who resigned to become associated with Eli Lilly & Co.—Dr. John D. Van Nuys, Indianapolis, has been named director of admissions at the Indiana University Medical Center, Indianapolis, a position created to centralize admissions to the various units of the center, according to an announcement.

IOWA

Faculty Changes at the University.—Dr. William Malamud, professor of psychiatry at the State University of Iowa College of Medicine, Iowa City, has resigned to become clinical director and director of research at the Worcester State Hospital, Worcester, Mass. Dr. Alton E. Braley, formerly instructor in ophthalmology, has been appointed assistant professor of ophthalmology at Wayne University College of Medicine, Detroit. The following faculty promotions have also been announced:

Dr. Wilbur R. Miller, to be associate professor of psychiatry.
Dr. Olan R. Hyndman, associate professor of surgery.
Dr. John W. Dulin, assistant professor of surgery.
Dr. Jacques S. Gottlieb, assistant professor of psychiatry.
Dr. Adolph L. Saks, assistant professor of neurology.
Titus C. Evans, Ph.D., research assistant professor of radiology.

KANSAS

Physicians in Civic Posts.—Dr. Harry Lutz, Augusta, was recently elected president of the Augusta Board of Education. Two other physicians are in civic posts: Dr. Samuel N. Mallison is president of the Augusta Chamber of Commerce and Dr. Fred A. Garvin is mayor.

Changes in Health Officers.—Dr. Herbert R. Schmidt, Newton, has been appointed health officer of Harvey County to fill the unexpired term of the late Dr. William F. Schroeder.—Dr. Adelbert R. Chambers, Iola, has been appointed health officer of Allen County, it is reported.—Dr. Howard F. Craig, Protection, has recently been appointed health officer of Comanche County.

Society News.—The Golden Belt Medical Society was addressed in Manhattan July 6 by Drs. Bernard W. Carey Jr., Detroit, on "Sulfapyridine in the Treatment of Pneumonia" and Charles C. Dennie, Kansas City, Mo., "Skin Infection in

Children."—The Central Kansas Medical Society was addressed in Ellsworth recently by Drs. James A. Wheeler, Newton, on "Study of Maturation and Its Clinical Application" and Claude J. Hunt, Kansas City, Mo., "Surgical Treatment of Benign and Malignant Lesions of the Stomach." Dr. Leroy A. Calkins, Kansas City, Mo., showed a motion picture on "Normal Obstetrical Procedures."

KENTUCKY

Pediatric Conference.—A pediatric conference will be held in conjunction with the annual session of the Kentucky State Medical Association in Bowling Green September 11. Speakers at a morning session will be: Drs. Richard G. Elliott II, Lexington, on "Bacillary Dysentery in Infancy and Childhood"; William Clark Bailey, Harlan, "Excessive Infant Feeding"; Jacob J. Glaboff, Louisville, "Lead Poisoning in Children" and William K. Keller, Louisville, "Practical Aspects of Children's Problems." In the afternoon Dr. Philip F. Barbour, Louisville, will conduct a clinic and Dr. James H. Pritchett, Louisville, a round table conference on pneumonia.

MAINE

State Medical Election.—Dr. Thomas A. Foster, Portland, was chosen president-elect of the Maine Medical Association at the recent annual meeting at Poland Spring and Dr. George L. Pratt, Farmington, was installed as president. Fifty year medals were presented to Drs. Charles B. Sylvester and Gustav A. Pudor, Portland; Bernard A. Bailey, Brunswick; Henry I. Durgin, South Eliot, and Gilbert M. Elliott,

MARYLAND

Dr. Rowland Retires as Dean.—Dr. James Marshall Hanna Rowland, since 1916 dean of the University of Maryland School of Medicine, Baltimore, retired with the title of dean emeritus at the end of the academic year, according to Science. A native of Maryland, Dr. Rowland graduated at Baltimore Medical College in 1892 and was professor of obstetrics there from 1900 to 1913. He occupied a similar position at the University of Maryland School of Medicine from 1920 to 1937 in addition to the deanship. He was president of the Medical and Chirurgical Faculty of Maryland in 1930-1931.

Grants to Johns Hopkins.—Within the last few months the Rockefeller Foundation has awarded two grants of \$350,000 and \$90,000 each to Johns Hopkins University School of Medicine, Baltimore. The larger is to be used over a ten year period to equip and maintain a department of preventive medicine while the second grant will be utilized as a research fund to be distributed among departments and to projects which stand in greatest need of aid in carrying out research programs, according to the university Gazette. A grant of \$2,000 was given by the Finney-Howell Research Foundation to advance biologic experiments now under way and which will be expanded with the completion of a new atom-smashing machine. Ultimately the school of medicine and Johns Hopkins Hospital will receive more than \$1,000,000 through a bequest by the late Victor Morawetz. The bulk of Mr. Morawetz's estate at the expiration of life interests held by immediate relatives is to be divided among three agencies: the Boys' Club of New York, Medical Society of South Carolina and Johns Hopkins.

MICHIGAN

New Health Unit.—A new full time health department has been organized in St. Joseph County. Dr. Lawrence A. Berg, Menominee, former director of the Menominee County health department, has been placed in charge of the new unit with headquarters at Centerville.

Collection of Obsolete Instruments.—The Detroit Historical Museum is attempting to collect surgical, dental and pharmacy instruments now considered obsolete, according to the Detroit Medical News. Donations will be appreciated and full credit will be allowed in the display.

Poliomyelitis Report.—Eleven new cases of poliomyelitis reported during the twenty-four hours ended Saturday morning, August 19, brought the total in Detroit since January 1 to 219. Health officials reported the wave has apparently "leveled off," with an average of ten cases a day. At the time of the report there were eighty-six active cases in the city. There had been eight deaths. It was expected that a decision would be reached by August 31 concerning the opening of schools, scheduled for September 6. Outside Detroit, thirty-one cases had been reported in the state up to August 18.

Changes in Foundation Staff.—Five special consultants have been appointed for the W. K. Kellogg Foundation, Battle Creek, newspapers reported July 18. They are:

Dr. Cyrus C. Sturgis, professor of internal medicine and chairman of the department, University of Michigan Medical School, Ann Arbor.
Dr. John E. Gordon, professor of preventive medicine and epidemiology, Harvard University Medical School, Boston.
Dr. Grant Fleming, dean of the faculty, Strathcona professor and head of the department of public health and preventive medicine, McGill University Faculty of Medicine, Montreal.
Dr. William S. Sadler, Chicago.
Dr. Wilson G. Smillie, professor of public health and preventive medicine, Cornell University Medical College, New York.

It was also reported that five other physicians had joined the staff of the foundation under fellowships: Drs. Edwin H. Place, Midland; Gennaro Basilicato, Blairstown, N. J.; Lorin E. Kerr, Toledo, Ohio; Kenneth W. Navin, Ann Arbor, and James M. Mather, Toronto, Ont. They will work in the seven counties covered by the community health project sponsored by the foundation, it was stated.

MINNESOTA

Northern Minnesota Meeting.—The annual meeting of the Northern Minnesota Medical Association will be held in Detroit Lakes September 8-9. Speakers on the first day's program will include:

Dr. Joel C. Swanson, Fargo, N. D., Use of Metal in Fractures.
Dr. Gordon R. Kamman, St. Paul, Painful Conditions About the Head and Face.
Dr. Chester L. Oppegaard, Crookston, Nasal Obstruction: Is It Allergic?
Dr. Leo G. Rigler, Minneapolis, Roentgen Diagnosis in Acute Abdominal Conditions.
Dr. Edward A. Meyerding, St. Paul, The Annual Session of the American Medical Association.
Dr. Thomas O. Young, Duluth, Infectious Diseases of the Thyroid.

Saturday's program will be a clinical pathologic conference under the direction of Dr. Edward L. Tuohy, Duluth. Dr. Frank J. Hirschboeck, Duluth, will be toastmaster at a banquet Friday evening at which State Senator A. O. Sletvold, Detroit Lakes, will speak on "The Trend of the Times."

MISSISSIPPI

Society News.—At a meeting of the Coast Counties Medical Society in Pascagoula recently Dr. James H. Dodson, Mobile, Ala., spoke on "The Anatomical Structures Dealt with in Treating Anorectal Diseases."—The South Mississippi Medical Society was addressed in Hattiesburg recently by Drs. Idys Mims Gage and Eugene H. Countiss, both of New Orleans, on "Acute Traumatic Subcutaneous Injury of Abdominal Viscera" and "Chronic Cervicitis" respectively. Dr. Nollie C. Felts, Hattiesburg, reported a case of abdominal pregnancy. —Drs. James J. Pittman, Tybertown, discussed dysenteries in children before the Tri-County Medical Society recently; Oscar W. Bethea, New Orleans, bronchiectasis, and Arthur Neal Owens, New Orleans, care of wounds.

MISSOURI

Society News.—At a meeting of the Cape Girardeau County Medical Society in Cape Girardeau recently Drs. Charles W. Duden, St. Louis, discussed "Irritable Colon" and Warren R. Rainey, St. Louis, "Early Diagnosis of Anorectal Diseases." —The Six County Medical Society was addressed in Sikeston recently by Drs. Garold V. Stryker and Carliss Malone Stroud, both of St. Louis, on common diseases of the skin and hay fever, respectively.

Award of Merit Goes to Neuropsychiatrist.—The Award of Merit of the St. Louis Medical Society will be presented to Dr. William W. Graves, professor and director of the department of neuropsychiatry, St. Louis University School of Medicine, in the fall. Dr. Graves was selected for the award "in consideration of the results of his studies on inherited variations in relation to the problems of the human constitution." According to the report, Dr. Graves was the first to classify shoulder blades into types and to apply that classification to determining potentialities for health and disease. Dr. Graves graduated at the St. Louis University College of Physicians and Surgeons in 1888. He has been on the faculty of St. Louis University School of Medicine since 1905, becoming professor of nervous and mental diseases in 1914 and director of the department in 1925.

NEW YORK

Personal.—Dr. Harry J. Brayton has resigned as superintendent of the Onondaga County Sanatorium, Syracuse. He has held the position for more than twenty years.—Dr. George A. Marsden, Oswego, has been appointed city health officer to succeed the late Dr. James E. Mansfield.

Course on Dietetics.—The council committee on public health and education of the Medical Society of the State of New York announces that a four day institute on dietetics will be held in the fall at Syracuse, with the cooperation of the state department of health, the Syracuse University College of Medicine and College of Home Economics and the New York Dietetic Association. Each topic on the program will be discussed by a physician and a dietitian. Following a general consideration of diet, the topics will be: diet in pregnancy and lactation, infancy and childhood, deficiency diseases, cardiac disease and arthritis, metabolism (diabetes, obesity and undernutrition), diseases of the gastrointestinal tract, renal diseases, allergy, surgery, food fads and fallacies. A registration fee of \$10 will be charged. Further information may be obtained from Dr. Thomas P. Farmer, chairman of the committee, 206 Sedgwick Drive, Syracuse.

OHIO

Dr. Zuck Heads Brush Foundation.—Dr. Theodore T. Zuck, a member of the staff of the Brush Foundation, Cleveland, since its establishment in 1929, has been appointed director to succeed the late Dr. T. Wingate Todd. Dr. Zuck graduated from Western Reserve University School of Medicine, Cleveland, in 1928.

Personal.—Dr. Will Maurice Hoyt, Hillsboro, has been appointed a member of the State Medical Board of Ohio to succeed Dr. Floyd S. Meck, Cleveland, whose term expired. —Dr. Kenneth Earl Shawker, Dover, was the guest of honor at an outing given by the Tuscarawas County Medical Society recently, marking his retirement after twenty-five years of practice.

Society News.—Dr. Daniel G. Caudy, Zanesville, discussed sulfapyridine therapy at a meeting of the Perry County Medical Society, New Lexington, July 20. —Dr. Harve M. Clodfelter, Columbus, spoke on "Arterial Diseases" before the Washington County Medical Society, Marietta, July 12. —Dr. Walter M. Simpson, Dayton, will address the Mahoning County Medical Society, Youngstown, September 19 on "Artificial Fever Therapy."

OKLAHOMA

Health Officers Appointed.—Appointment of the following county health officers has recently been announced:

Dr. Francis Polk Fry Jr., Frederick, of Tillman County.
Dr. James C. Runley, Sigler, Haskell County.
Dr. John I. Derr, Waurika, Jefferson County.
Dr. Simon S. Garrett, Duncan, Stephens County.
Dr. Lloyd T. Lancaster, Cherokee, Alfalfa County.
Dr. Loren V. Baker, Elk City, Beckham County.
Dr. William F. Griffin, Watonga, Blaine County.
Dr. Robert K. McIntosh Jr., Tahlequah, Cherokee County.
Dr. Joshua P. Beam, Arnett, Ellis County.
Dr. William S. Cary, Reydon, Roger Mills County.
Dr. Walter R. Joblin, Porter, Wagner County.
Dr. Hugh H. Monroe, Lindsay, Garvin County.
Dr. Ferdinand R. Hassler, Jr., Seminole, Pottawatomie County.

OREGON

State Medical Meeting at Gearhart.—The Oregon State Medical Society will hold its sixty-fifth annual meeting in Gearhart September 6-9 under the presidency of Dr. Charles E. Sears, Portland. Guest speakers, who will make three addresses each and lead round table discussions, will be:

Dr. Clifford J. Barborka, Chicago, Recent Advances in Nutrition; Management and Treatment of Obesity; Diagnosis and Treatment of Peptic Ulcer.
Dr. Otto H. Schwarz, St. Louis, The Possible Causes, Prophylaxis and Treatment of the Toxemias of Pregnancy; Care of Postpartum Infections; Management of Breech Presentations.
Dr. Nathan A. Womack, St. Louis, Jaundice, Its Surgical Significance; Silent Gallstone and Symptoms of Cholecystitis; Cancer of the Breast.
Dr. Alexis F. Hartmann, St. Louis, Infant Feeding; Present Status of Chemotherapy with Sulfanilamide and Derivatives; Some Practical Aspects of Parenteral Fluid Administration.

Among Oregon physicians who will take part in the program are:

Dr. Frederick A. Kiehle, Portland, Opacities of the Cornea and Their Treatment.
Dr. Henry H. Dixon, Portland, Practical Therapy for Anxiety Tension States.
Dr. Max W. Hemingway, Bend, Coronary Occlusion as Encountered in General Practice.
Dr. Frank Perlman, Portland, Practical Approach to Management of Allergic Skin Disorders.
Dr. Clarence I. Drummond, Medford, Edema of the Head and Neck: A Symptom in Calcified Pericardium.
Dr. Karl H. Martzloff, Portland, Cancer of the Fallopian Tubes.

The thirteenth annual golf tournament will be held Saturday September 9 on the Gearhart course. The annual banquet will be Friday evening September 8.

PENNSYLVANIA

Society News.—Dr. Walter A. Bloedorn, Washington, D. C., addressed the Cambria County Medical Society, Johnstown, July 13 on "Practical Aspects, Diagnosis and Treatment of Heart Disease." —Dr. Harrison S. Martland, chief medical examiner of Essex County, Newark, N. J., was guest speaker at the annual meeting of the Lehigh Valley Medical Association at the Pocono Manor Inn, July 20. His subject was "Dr. Watson and Mr. Sherlock Holmes." Dr. Martin S. Kleckner, Allentown, delivered his presidential address on "Overspecialization in Medicine."

District Meeting.—The Eleventh Councilor District of the Medical Society of the State of Pennsylvania held a meeting at Uniontown July 19. Speakers on the morning program were: Drs. Walter M. Bortz, Greensburg, on pneumonia; David H. Ruben, Washington, "Pertinent Facts in Present Day Urology"; Elliott B. Edie, Uniontown, "The Physician as a Patient"; Leo W. Hornick, Johnstown, "Skull Fractures," and James E. Van Gilder, Uniontown, "Diabetes—the Family Physician's Problem." In the afternoon Dr. Eugene R. Whitmore, Washington, D. C., spoke on "Chronic Cystic Mastitis and Carcinoma of the Breast"; Drs. David W. Thomas, Lock Haven, president of the state society, and Walter F. Donaldson, Pittsburgh, secretary, discussed medical activities. A fifty year testimonial was presented to Dr. William L. Dodd, Amity. Dr. Donaldson, Dr. Thomas and Mrs. Donaldson, who is president of the state auxiliary, addressed a meeting of the woman's auxiliaries of the district.

Philadelphia

Dr. Martin Appointed Professor at Jefferson.—Dr. James R. Martin, chief surgeon at the State Hospital for Crippled Children, Elizabethtown, and director of the state program for crippled children under the Social Security Act, has been appointed James Edwards professor of orthopedic surgery at Jefferson Medical College. He succeeds Dr. J. Torrance Rugh, who has resigned after holding the chair since 1918 and who will become professor emeritus. Dr. Martin graduated from Jefferson in 1910 and was continuously associated with the college and with Jefferson Hospital until 1938, when he accepted the state appointment. He was assistant professor of orthopedic surgery at the medical school and chief of the hospital's outpatient orthopedic clinic at that time.

RHODE ISLAND

Hospital Superintendents Appointed.—Dr. Charles P. Fitzpatrick, clinical director of Butler Hospital, Providence, has been appointed superintendent of the State Hospital for Mental Diseases at Howard, succeeding Dr. Seth F. H. Howes, resigned. —Dr. Ubaldo E. Zambarano, assistant to the director of the Providence Tuberculosis League for the past ten years, has been appointed superintendent of the State Sanatorium, Wallum Lake. He succeeds Dr. Hilary J. Connor.

SOUTH CAROLINA

District Meeting.—The Second District Medical Society met in Aiken July 27 with the following speakers: Drs. Austin T. Moore, Columbia, on "Basic Principles in Fracture Treatment"; Walter E. Daniel, Charlotte, N. C., "A Comparison of Sulfanilamide, Sulfanyl-Sulfanilamide and Sulfapyridine," and William A. Mulherin, Augusta, "Preventive Pediatrics."

UTAH

Personal.—Dr. William M. McKay, Salt Lake City, director of the division of communicable disease control of the state board of health, has been made acting state health commissioner to serve for two years while Dr. John L. Jones, the health commissioner, is conducting a survey of occupational disease in the state. —Dr. Lewis F. Seapy, San Francisco, has been appointed medical superintendent of a new Utah Tuberculosis Sanatorium at Ogden.

VIRGINIA

Society News.—Dr. Wellford C. Reed, Richmond, addressed the Dickenson-Buchanan Counties Medical Society, Grundy, recently on "Use of Digitalis and Quinidine in Heart Conditions." Dr. John P. Williams, Richmond, showed a film on the heart. —Dr. Hugh H. Trout, Roanoke, president-elect of the Medical Society of Virginia, addressed the Patrick Henry Medical Society at its quarterly meeting in Martinsville, July 14 on the work of the state society and the American Medical Association.

WISCONSIN

MEDICAL NEWS

867

Changes in Medical Board.—Dr. Harold W. Shutter, Milwaukee, has been appointed to the state board of medical examiners to succeed Dr. Henry J. Gramling, Milwaukee, and Dr. Jessie P. Allen, Beloit, to succeed Dr. Henry W. Howe, Racine. A special meeting of the board will be held September 14 to elect a new secretary and to consider applicants for licenses by reciprocity.

Lectures on Viruses.—Dr. Christopher H. Andrewes, a member of the British Medical Research Council, gave a series of lectures at the University of Wisconsin Medical School, Madison, July 25-28, under the auspices of the Wisconsin Alumni Research Foundation. His subjects were: "The Nature and Properties of Viruses," "Viruses in Relation to New Growths," "Recent Work in Influenza" and "Immunity in Influenza and Other Virus Infections."

GENERAL

Another Million for Infantile Paralysis Fund.—The Committee for the Celebration of the President's Birthday reported August 10 to President Roosevelt that the 1939 drive for funds to aid in fighting infantile paralysis netted \$1,329,100. The National Foundation for Infantile Paralysis, Inc., organized this year on a nationwide basis, will administer the fund, half of which is to be used for research and the remaining half to be sent to local chapters. The largest part of the proceeds of the drive came from the birthday balls and other events held January 30. The "March of Dimes" campaign raised \$217,602.28 and other contributions amounted to \$96,971.58.

Clifford Beers Resigns from Mental Hygiene Committee.—Mr. Clifford W. Beers, New York, founder of the mental hygiene movement, has resigned as secretary of the National Committee for Mental Hygiene after more than thirty years of service. He will continue his work as secretary of the American Foundation for Mental Hygiene and the International Committee for Mental Hygiene. The National Committee announces the appointment of Dr. Milton E. Kirkpatrick, New York, recently director of a child guidance center at Lansing, Mich., as director of the division on community clinics to succeed Dr. George S. Stevenson. Dr. Stevenson recently became medical director of the national organization.

Special Society Elections.—Dr. Adrian V. S. Lambert, New York, was elected president of the American Association of Thoracic Surgery at its annual meeting in Los Angeles July 5-7. Dr. Fraser B. Gurd, Montreal, Canada, was elected vice president; Dr. Richard H. Meade Jr., Philadelphia, secretary, and Dr. Isaac A. Bigger, Richmond, Va., treasurer. Dr. Henry D. Chadwick, Waltham, Mass., was elected president of the National Tuberculosis Association at the recent annual meeting in Boston. Drs. Paul H. Ringer, Asheville, N. C., and David O. N. Lindberg, Decatur, Ill., were elected vice presidents and Dr. Charles J. Hatfield, Philadelphia, was reelected secretary. The 1940 meeting will be held in Cleveland during the week of June 3.

Cancer Congress in Atlantic City.—The Third International Cancer Congress will be held in Atlantic City, N. J., September 11-15, at the Haddon Hall Hotel under the presidency of Dr. Francis Carter Wood, New York. Sections of the congress and their chairmen are as follows: Biophysics, Gioacchino Failla, D.Sc., New York; Genetics, Clarence C. Little, Sc.D., Bar Harbor, Maine; Experimental pathology, Dr. William H. Woglom, New York; General pathology, Dr. Milton C. Winternitz, New Haven, Conn.; Surgery, Dr. Frank H. Lahey, Boston; Diagnostic roentgenology, Dr. John D. Camp, Rochester, Minn.; Therapeutic radiology, Dr. Ursus V. Portmann, Cleveland; Statistics and education, Dr. Burton T. Simpson, Buffalo; General section, Dr. Francis Carter Wood, New York.

Each evening lectures will be presented surveying some special field. Included in these lectures will be one by Dr. Thomas W. Mason, Surgeon General, U. S. Public Health Service, Washington, D. C., on "Cancer and the Public Health" and one by Dr. James Ewing, New York, on "Cancer, Present and Future."

Sanatorium Association Changes Name.—The American Sanatorium Association at its annual meeting in Boston in June widened its scope and functions and changed its name to the American Trudeau Society. The American Sanatorium Association was organized in 1905 by physicians associated with sanatoriums. The reorganization provides for inclusion of many physicians outside of sanatoriums who have active interest in tuberculosis and other diseases of the chest. The society will continue to conduct its programs in conjunction

with those of the National Tuberculosis Association and will assume responsibility for the clinical and pathologic programs of the latter, according to an announcement. Dr. James Burns Amberson Jr., New York, is the president of the American Trudeau Society; Dr. Lewis J. Moorman, Ann Arbor, Mich., president-elect; Dr. John B. Barnwell, Waverly Hills, Ky., secretary, and Dr. Benjamin L. Brock, Waverly Hills, Ky., secretary.

Changes in Status of Licensure.—The Alaska Board of Medical Examiners recently reported the following action: Dr. Morris P. Kaufman, whose present address is Simnasho, Ore., licensed revoked June 2, following revocation of his California license on a charge of narcotic addiction. His Alaska license was granted by reciprocity with California.

The New York State Board of Medical Examiners has reported the following actions in recent months: Dr. Alexander Neshamkin, New York, license reinstated; it was suspended May 20, 1938. Dr. Peter H. Friedman, New York, license reinstated; it was suspended July 29, 1938. Dr. Victor Laub Gross, formerly of New York, license reinstated; it was suspended July 29, 1938. Dr. Joseph N. Zinkoff, New York, license reinstated after a suspension from January 27, on the ground of an attempted abortion. Dr. Solomon Netzer, Brooklyn, license suspended for nine months February 24, based on conviction of conspiracy. Dr. Samuel Reich, Brooklyn, license suspended for one year from January 27, on the basis of fraud and deceit. Dr. Herman Renkoff, now of Crestview, Fla.; license suspended for six months from January 27, on his conviction of the crimes of conspiracy and petit larceny. Dr. John J. Van Horn, New York, license suspended for one year from March 17 for fraud and deceit in that he aided and abetted the practice of an unlicensed practitioner. Dr. Leon Luria, New York, license suspended for one year from April 21 for fraud and deceit in the practice of medicine.

Fraudulent Salesman—Uniforms.—Physicians are warned to watch for one Ward Osborne, who claims to represent the Angelica Jacket Company, manufacturers of uniforms. The firm reports that complaints have been received from Iowa, Wisconsin and Illinois that the man is not and never has been on its sales staff. Osborne carries samples and a catalogue from the Angelica firm. He demands a down payment and also says that if full payment is made the firm will pay the postage. The Angelica company points out that its representatives do not sell to individuals and do not receive down payments on merchandise. Osborne is described as being about 6 feet tall, weighing about 180 pounds, having brown eyes and dark complexion and being well dressed.

Railway Surgeons' Meeting.—The fiftieth annual meeting of the American Association of Railway Surgeons will be held at the Palmer House, Chicago, September 11-13, under the presidency of Dr. Mathew A. Tinley, Council Bluffs, Iowa. Among the speakers will be: Dr. John R. Nilsson, Omaha, Open Reduction of Severe Fractures. Dr. Sanford R. Gifford, Chicago, Eye Injuries and Their Management. Dr. Roland M. Klemme, St. Louis, Trigeminal Neuralgia, Accurate Differential Section with the Preservation of the Ophthalmic Branch. Dr. George W. Hall, Chicago, Routine Neurologic Examination. Dr. Ralph M. Dodson, Portland, Ore., Fractures of Transverse Processes of Lumbar Vertebrae. Dr. John H. Alexander, Pittsburgh, Pathologic Fractures in Relation to Industry. Dr. Gordon B. Myers, Detroit, Prediction of Coronary Accidents. Dr. Harry V. Spaulding, New York, Injuries to the Semilunar Cartilage.

Association of Obstetricians and Gynecologists.—The fifty-second annual meeting of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons will be held at The Homestead, Hot Springs, Va., September 7-9 under the presidency of Dr. James E. King, Buffalo. Among the speakers on the program will be: Dr. Walter B. Mount, Montclair, N. J., An Electric Timer: An Aid in Counting the Fetal Heart in the Second Stage of Labor and in Spacing the Timing Forceps Tractions. Dr. James K. Quigley, Rochester, N. Y., Maternal Welfare Work—What Are Its Fruits? Dr. Herbert E. Schmitt, Chicago, Hermaphroditism. Dr. James R. Goodall, Montreal, Canada, A Study of Uterine Defense Mechanisms. Dr. William Seaman Bainbridge, New York, The Inter-Relationship of Surgical Conditions of the Pelvic and Abdominal Viscera. Dr. Robert D. Mussey, Rochester, Minn., Report of an Investigation of the Clinical Relationship of Pelletis of Pregnancy to Preeclamptic Toxemia. Dr. Joseph W. O'Connor, Worcester, Mass., Spontaneous Rupture of the Uterus.

The association's Foundation Prize will be awarded to Dr. Abraham R. Abarbanel, Bronx, N. Y., who will present his thesis on "The Therapeutic Rationale for the Use of Testos-

terone Propionate in the Immediate Treatment of Functional Uterine Bleeding." The Joseph Price Oration will be delivered Thursday evening September 7 by Prof. Paul Werner, Vienna, on "Conservative Operations per Vagina with Details of Modern Technic." At the annual banquet Friday evening September 8 the speaker will be Hon. A. Willis Robertson, Lexington, Va., congressman from the seventh Virginia district.

CANADA

Canadian Medical Election.—Dr. Duncan Graham, Toronto, was chosen president-elect of the Canadian Medical Association at the annual meeting in Montreal in June and Dr. Frank S. Patch, Montreal, was installed as president. The next meeting will be in Toronto.

Faculty Changes.—Appointments announced by the University of Manitoba Faculty of Medicine, Winnipeg, include the following: Drs. James D. Adamson, to be professor of medicine; Oliver S. Waugh, professor of surgery; James D. McQueen, professor of gynecology, and Rosslyn B. Mitchell, professor of obstetrics.—At the University of Montreal Faculty of Medicine Dr. Leon Gerin-Lajoie has been appointed professor of gynecology and Drs. Roma Amyot and Jean Saucier, professors of neurology.

FOREIGN

British Medical Election.—Sir Harold Beckwith Whitehouse, Birmingham, was chosen president of the British Medical Association at the annual meeting in Aberdeen in July and Dr. Thomas Fraser was installed as president. Sir Ernest Kaye Le Fleming, Wimborne, chairman of the council for several years, was elected a vice president. Next year's meeting will be in Birmingham.

Congress on Child Welfare.—The fourteenth session of the International Association for the Promotion of Child Welfare will be held in Rome October 9-14. There will be three sections: medical, legal and social. The topic for the medical section will be prevention of tuberculosis in susceptible children. A program may be obtained from the secretary-general, 67, avenue de la Toison d'Or, Brussels.

Society News.—The Italian National Congress of Obstetrics and Gynecology will be held in Turin October 15-18. The official topics are gynecologic symptoms of extragenital diseases and ovarian hormone treatment in obstetrics and gynecology.—A course in balneology will be offered by the Hungarian Postgraduate Medical Education Committee in Budapest October 2-8. The program will be sent on request to the committee, Esterhazy-utca 9, Budapest VIII.

Government Services

Dr. Akin Appointed Assistant Surgeon General

Dr. Charles V. Akin, chief quarantine officer of the Port of New York since 1936, has been detailed as assistant surgeon general of the U. S. Public Health Service in charge of the division of sanitary reports and statistics. Dr. Akin, a native of Mississippi, graduated from Tulane University of Louisiana School of Medicine in 1911 and entered the Public Health Service in 1914. He has had varied service in the fields of states relations, rural sanitation, bubonic plague and foreign quarantine activities. During the World War he was in epidemiologic work in army camps.

Medicomilitary Inactive Status Training

The eleventh annual inactive status training course for medical department reservists of the U. S. Army and Navy will be held at the Mayo Foundation, Rochester, Minn., October 8-22. As in former years, special work in clinics and hospitals will be offered during the morning hours for those asking special assignments. Presentations of selected subjects in military medicine are scheduled. There will be appropriate sections or special courses for officers of the dental and veterinary corps. All medical department reservists are eligible for enrollment. Approved applicants will be enrolled on the recommendation of the surgeon of the seventh corps area or the surgeon of the ninth naval district. Applications should be made at an early date and should be forwarded through the respective reserve headquarters of the officers concerned.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Aug. 3, 1939.

The Problem of Medical Literature

In correspondence in the *Lancet* on the problem of medical literature, Prof. R. J. S. McDowell declared that the present state is chaotic and has been continued by medical writers on the one side and by medical librarians on the other. Professor McDowell supposes the case of a physician who has an idea and wants to find out what has already been done on a subject. He writes to the librarians of the Royal Society of Medicine, if he is a member. They consult the *Quarterly Cumulative Index Medicus* and the Surgeon General's Catalogue and in due course a list of some hundreds of references, in all manner of languages, arrives. Some are relevant, many are not. He tries to find out where the journals are, and if he is lucky enough to find them they will prove to be scattered over the libraries of Britain; some are already on loan and some in libraries which do not lend. Many libraries take the same journals and most have to restrict their intake to what they can afford. Having obtained a journal, which may be in Hungarian, he has to find a translator and then the paper may prove not to be relevant. And so he goes on until his enthusiasm is quenched.

Professor McDowell pleads for more coordination between libraries to make the lesser known journals more accessible. In London there are fourteen general medical libraries. There is need for an adequate medical abstracting journal, such as exists for chemistry and physiology. Mr. G. A. Lloyd, librarian to the British Postgraduate School, suggests that this work should be undertaken by some body such as the British Medical Association. "Its sister association across the water presents the profession with the most valuable bibliographic tool it has." A surgeon, Mr. Zachary Cope, describes the present state of medical literature as "disheartening" and advocates that there should be one large library where all the rarer and more expensive journals could be taken and which should work in close cooperation with all other medical libraries. It would need a special staff for preparing references and translating and be equipped for photostatic and photomicrographic reproduction. Mr. C. C. Barnard, librarian of the London School of Tropical Medicine, points out that the Library Association is compiling a list of all known medical periodicals, of which there are probably about 7,000, on specially printed cards with a place for recording the holdings of all the British scientific libraries. The next step will be to cancel redundant subscriptions and with the money saved buy other periodicals not now available. Mr. Le Fanu, librarian of the Royal College of Surgeons, says that Britain has an unrivaled wealth of medical libraries but that they are not coordinated and do not cover the whole field. In London four medical libraries have begun to cooperate and are coordinating their subscriptions. He advocates coordination in preference to establishing a central library.

Heparin in Prevention of Thrombosis

At a meeting of the Section of Surgery of the Royal Society of Medicine Dr. Gordon Murray of Toronto described his work on heparin, which he had done in collaboration with Prof. C. H. Best. Heparin was first isolated by MacLean in 1916. When struggling with some work on blood vessel anastomosis Murray found that most of his failures were due to coagulation and it was suggested to him that Best had a substance, heparin, which would prevent clotting. They then began to investigate the problem. From 100 pounds (45 Kg.) of

beef lung they isolated 1 Gm. of heparin, which is the strongest organic acid known. Much work was done before it was finally produced as a crystalline barium salt. When the superficial veins of dogs were occluded they remained patent in 90 per cent of cases if heparin was given. If a vein was grafted into an artery, thrombosis occurred in a few hours; but under heparin the grafts remained patent for from seven to ten days. A thrombus produced by inserting a foreign body at the bifurcation of the femoral artery could be successfully removed in the heparinized animal after it had remained in situ for twenty-four hours and become attached to the intima. A valve of the heart had been removed and a new valve substituted and the animal lived without a thrombus being formed.

CLINICAL APPLICATIONS

Heparin had been given by continuous intravenous drip to more than 400 patients without toxic effects. A large number of the cases were postoperative in the attempt to prevent pulmonary embolism. Major operations, such as gastrectomy, were well represented. Among these the postoperative mortality from pulmonary embolism ranged from 2 to 7 per cent, but in the heparinized subjects it was nil. All that heparin did was to prevent the formation of a clot; it did not absorb a clot already formed. Heparin had proved useful in cases of pulmonary embolism. In cases in which there had been one attack of embolism there were practically always other emboli waiting to be discharged. There was now a series of twenty-two cases of repeated pulmonary embolism, with survival under heparin, and with one possible exception there had been no further embolism. Some of the patients died from other causes and no sign of embolism was found post mortem.

Six patients with mesenteric thrombosis had been treated with heparin and four were alive and well after resection of the intestine varying from 1½ to 7 feet. The mortality of splenectomy was very high, almost always from mesenteric thrombosis, but the few patients who had been treated with heparin survived. If the coronary artery was not occluded at the beginning of an attack of coronary thrombosis, heparin might prevent occlusion.

In the discussion the chairman, Mr. Claude Frankau, congratulated Dr. Murray on the brilliance of his work and confirmed the value of heparin in embolectomy. Other speakers reported remarkable results, but complaint was made as to the cost of heparin. Dr. Murray said that this difficulty existed also in Toronto. He was afraid that the price would not be lower until a synthetic preparation came on the market.

Hospitals in War Time

The scale on which the government is making war preparations in the hospitals can be judged by the fact that it is already committed to an expenditure of \$32,000,000. At a conference of the chairmen of the London teaching hospitals Mr. Elliot, minister of health, said that in an emergency 100,000 existing beds in England and Wales would be cleared and made available for casualties. Additional beds to be introduced had been manufactured and were in hand. The work of adaptation necessary for upgrading had been settled at almost all the hospitals, in the majority of cases at government expense. More than 40,000 additional hospital beds were being provided in hutments. Group officers, appointed by the hospitals, had been at work for four months in the London sectors on the distribution among the expanding hospitals of the available medical personnel. Auxiliary nurses were being steadily recruited and trained to the number of 60,000 so far for the whole of Great Britain. Proposals on the finance of the treatment of casualties had been submitted to the hospitals. Flat rate payments per casualty would be made and regarded as interim payments subject to review. If any hospital should be so financially embarrassed that it could not provide the

casualty service required of it, the government would provide such financial accommodation as might be necessary. It was agreed that the chairmen of the hospitals should draw up a memorandum in detail on the points on which they wished guidance and decisions and that after this had been submitted to the minister they would, if he so desired, meet him again.

Medicine and Publicity

In a recent conference of physicians of the Bordeaux area, Professor Mauriac discussed the problem of publicity. His position as dean of the Bordeaux faculty permits him to say what he thinks. His point of view on this serious professional problem is interesting. An important group of French physicians maintain an uncompromising attitude toward open or disguised publicity, in which certain physicians and many pharmacists subtly engaged. A considerable number of practicing physicians criticize everything that smacks of inviting attention. For example, they are opposed to having the names of the heads of the departments with their consultation hours posted at the entrance of hospitals and to the scientific collaboration of the teaching staff of faculties of medicine with manufacturing industries. Mauriac criticizes this exclusive attitude as contrary to scientific activity. In France the government does but little for laboratories. Public services are poorly endowed. Gifts and foundations are numerous, but they would not suffice to maintain research workers if a few great industrialists did not devote a large part of their profits to laboratories and the endowment of chairs and professorships.

Mauriac, however, is of the opinion that the detachment of a physician with professorial status is a guaranty of independence worth all conceivable monetary bribes. Medicine, a liberal profession, should be taught by teachers who have a liberal mind and are jealous of their freedom to the point of repulsing what menaces it. "The honor of a teacher consists in a free mind, free hands and free speech toward the student as well as toward his colleagues and administrators."

An unobnoxious form of publicity expresses itself in flooding the physician with bill-folds, printed material of a professional nature and small gifts. Mauriac is not opposed to these attentions. But there are more troublesome features. Can one, for example, without lowering professional standards, attend a purely scientific gathering, organized, however, by a thermal water organization which pays all traveling and hotel expenses, or can one accept an invitation to a hunting party when one must suspect that the ulterior motive is to enlist interest for a drug? Can one write a scientific article for an otherwise unobjectionable periodical but which is sent gratuitously to 30,000 or 40,000 physicians? What difference is there between this article which serves a commercial purpose and articles which are published by large medical journals which, after all, depend on publicity for their existence? Often the decision can be made without hesitation; for example, if the request made is intended to help the sale of a medicament or includes a check. Industrialists who need the patronage of a physician connected with a teaching institute, or the support of practicing physicians, are good psychologists and often embarrass the professional conscience. Distrust is not hostility, he said, but it is necessary to be cautious. He concluded: "If publicity has a dangerous implication, it depends on us to protect ourselves like grown boys."

Confederation of French Medical Syndicates

The council of the confederation of French medical syndicates held its annual meeting July 9. The confederation represents the large majority of French physicians, divided into

numerous local groups. The expressions of its delegates are truly representative of French medical opinion. Only professional problems of a practical nature are discussed at these meetings; for example, the necessity of defending the medical profession against undertakings of the state and against machiavellian alliances of different organizations such as mutual societies that desire medical service cheaply and wish to harness French physicians who are traditionally individualistic and independent to joint action.

The debates, therefore, of the council reflect the thought of physicians on questions affecting their profession as a whole. Special attention was given to the measures taken by social insurance companies against the medical profession. In France physicians are always paid directly by their clients even though the clients are members of a social insurance company. Patients are reimbursed by commissions composed in equal number of physicians, representatives of insurance companies and delegates of sick funds. Reimbursement is made in accordance with a minimum tariff representing, generally, half or two thirds of the fee paid to the physician. This arrangement was worked out to avoid abuses and to educate patients to the need of economy in medical matters. The extent of the contributions on the part of workers and their employers had been carefully worked out seven years ago at the time the law went into effect and equality of payment was adopted. In consequence, the sick funds have much money. The activating spirit is at bottom totalitarian and tends toward the socialization of medicine by different approaches and arrangements. These naturally encounter the vigilant opposition of the medical profession and their representatives. Such opposition, however, does not exclude cooperation. On the contrary, the medical profession recognizes that sick funds can do a great deal of good in the field of prophylaxis and hygiene. However, the syndicates wish strictly to control the organizations whose social value they appreciate. This surveillance does not suit the sick fund companies and results in friction.

Other discussions pertaining to the state concerned the large number of small provincial hospitals which are jealous of their autonomy. Their improvement and modernization is sought but no one wants to pay for it. On the other hand, the problem is recurrently rendered difficult by inherited situations and local difficulties.

The question of free dispensaries that depend on foundations or subsidies and are open to all, not only to the indigent, thereby competing with medical practice, comes up for discussion periodically as well as that of the extramedical publicity of pharmacists, the abuses of which are encouraged by the metropolitan press but which will some day have to be checked.

This year two new problems were brought before the representatives of the confederacy, that of curbing abortions and the use of the individual health book. As regards the former, the state can count on the support of the medical profession except if it makes it compulsory for physicians to report the cases brought to their attention. As regards the latter, it raises some difficulties relative to information confidentially given, but these, no doubt, can be adjusted.

Congress of French Gynecologists

The eighth Congress of French Gynecologists was attended by representatives of ten nations. Its meetings were presided over by Professor Bender of Paris, with Professor de Snod of Utrecht as honorary president. General Secretary Jayle indicated its particular field of interest; namely, parthenology. As gynecology deals with the grown woman, parthenology studies the organism of the maiden from the threefold point of view of heredity, morphology and physiology as well as the pathologic and therapeutic consequences connected with it. Disorders of girls in the early and adolescent age are becom-

ing increasingly frequent. The first paper, read by Noel of Lyons, was devoted to the embryology of the genital apparatus. Cordier of Lille and his collaborators presented their morphologic investigations of the feminine pelvis before puberty. The sex characteristic of the pelvis can be noted from the fifth month of intra-uterine life. Vanverts of Lille and his collaborators took for their subject the vagina at puberty. Acidification discoverable at puberty is strongly influenced by estrogenic secretions, which cause the accumulation of glycogen in the epithelium of the vagina and the development of Döderlein's bacillus. The vaginal hydrogen ion concentration is then in accord with the estrogenic function. This function was treated by Cordier of Lille and Turpault of Paris. Not only the secondary sexual traits but even the sex of the gonads is embryologically determined by the secretion of the genital hormones. The ovaries are not the only source of estrogenic substances nor are their secretions limited to estrogen. The concentration of estrogen in the blood is somewhat stronger in young girls than in women. There exist before puberty sketchy rudiments of the hormonal cycle, and estrogen increases abruptly at the time of the development of the breasts. Estrogen can be found also in the urine of young boys.

According to Paucot and Bédrine of Lille and other speakers, the effect of hereditary syphilis on the functions of the ovaries is positive in the great majority of cases. It makes itself felt in syphilitic changes in the ovaries. Delannoy and Démarez of Lille treated tumors of the genital apparatus of the young girl. These are accompanied at times by early sexual maturity in harmony with the endocrine activity of the tumor. Two disorders of the breast in young girls, massive hypertrophy and breast cysts, are amenable to endocrine therapy, especially testosterone. Often, however, plastic surgery is the only solution. Sabicandro of Rome discussed the microscopic anatomy of the vaginal mucosa in young girls; Palmer and Juliette Devillers discussed the therapy of primary dysmenorrheas.

The next meeting will be held at St. Malo in 1940 and the subject will be uterine fibromas.

Congress for Research on the Circulation of the Blood

This year's session of the Deutsche Gesellschaft für Kreislaufforschung was held in Bad Nauheim and was attended by about 600 physicians. Professor Edens of Düsseldorf presided. The electrocardiogram was the main subject of discussion of the first day. R. Elmquist of Lund, Sweden, discussed the methodology of the electrocardiogram. The physiologist E. Schütz pointed out that the monophasic electric current due to tissue activity appears when a pole becomes negative. Its significance lies in the fact that through it the formation of the electrocardiogram can be explained. A. Weber of Bad Nauheim pointed out that the electrocardiogram does not tell anything about the mechanical performance of the heart. It indicates that the contraction of the auricle is followed by that of the ventricle, also the place of origin and duration of the contraction. Local injuries of the cardiac muscle and certain coronary disturbances can be recognized. A sinking of the ST wave after infectious diseases and in attacks of angina pectoris is not easy to record. The continued sinking of the ST wave is an unfavorable sign. It is not easy to ascertain the true condition of the heart. Heart disease can remain unnoticed even until the appearance of cardiac asthma. M. Holzman of Zurich pointed out that the so-called middle infarct is caused by the occlusion of the ramus descendens anterior. The pathologist F. Büchner of Freiburg pointed out that by

the local anemia of the cardiac muscle electrocardiographic changes are created. They may change back when the local anemia is over.

The subject of the second day was the treatment of cardiac muscle injury. A. V. Allen of Rochester, Minn., reported on the results of sympathectomy in essential hypertension before the principal papers were read; only a certain group of hypertensive patients can be treated this way. The subjective complaints will also improve if the hypertension is not influenced. The headaches will improve 100 per cent, dyspnea while working 50 per cent, nervousness 80 per cent and fatigability 40 per cent. The surgical results with respect to decrease in blood pressure were 20 per cent failure, 28 per cent moderate results, in an additional 28 per cent transitory results and 24 per cent good results. From the Volhard clinic in Frankfort on the Main, on the other hand, Hildebrandt in twenty-seven cases did not obtain a decrease in blood pressure by decapsulation or by sympathectomy. Subjective improvements can easily appear. Judging from the experiences of this clinic, the surgical methods of treating high blood pressure are to be viewed with circumspection. The physiologist Broemser of Munich spoke on the different graphic records of cardiac contraction and pharmacologist Gremels of Marburg on the efficiency of the heart under the influence of different drugs. The greatest therapeutic effect was observed with digilanid C, one of the glucosides contained in digilanid. The internist Volhard of Frankfort spoke on the clinical aspects of this subject. Decompensation can be caused by different pathologic conditions: disease of the pericardium and myocarditis; as the therapy differs, the right diagnosis is essential. Cardiac and bronchial asthma are often taken one for the other in practice; in the first case injection of strophanthin may improve the condition; venesection and a small dose of morphine are useful. In all patients who lean toward cardiac asthma, liquids should be prohibited from noon on. In cardiac muscle insufficiency, the patient should lie elevated. Inhalation of oxygen (45 per cent) may cause rapid disappearance of the symptoms of decompensation. The diet must be salt free. Milk should not be given on account of its salt content. In right-sided insufficiency, squill is recommended in preference to digitalis or strophanthin.

The Advertising of Proprietary Foods

In the interests of public health, the propaganda council of Germany has formulated rules relating to the advertising of proprietary foods for infant feeding. The object of the government was to increase in mothers the joy of nursing and to urge them to nurse their babies in order to decrease the infant mortality. In advertising prepared foodstuffs one should keep in mind that mother's milk at an early age should be discontinued only in cases of emergency. Advertising is especially contrary to the interests of public health when it creates the impression that prepared foodstuffs completely take the place of mother's milk. It should be brought out clearly that artificial feeding is to be used only in case it is impossible to use mother's milk. The results attributed to prepared foodstuffs are often out of proportion to their intrinsic value. The consumption of albumin in Germany is not limited exclusively to fresh eggs but is covered to quite an extent by pulverized eggs, which have to be imported mostly from China. The yearly egg consumption of the German people averages about 118 eggs per person. This throws some light on the general food situation in Germany. In advertising preparations for the care of the teeth, the council points out that their effect on tartar is emphasized in a way to create the impression that the preparation in question removed and prevented the formation of tartar. This cannot yet be taken as proved. Restraint should be applied in such recommendations; individual cases of success should not be generalized.

Japanese-German-Italian Dictionary of Medicine

A Japanese-German-Italian dictionary of medicine will be published shortly in Japan. It has been compiled by Dr. Zen-setsu Ohja of the University of Kioto with the support of the Italian ambassador in Tokyo. Three and a half years was needed to compile this extensive dictionary.

Medical Fees Tribunal

The Queensland branch of the British Medical Association recently established a Medical Fees Tribunal, the purpose of which is to adjudicate on questions of dispute relating to medical fees. The tribunal consists of five members appointed by the council of the branch association at its first meeting every year and may act only on an official request from that council. Its function is to advise the council as to the justness of fees charged in any case placed before them, after all available information on the matter in question has been considered. For the purpose of ascertaining the facts of the matter in dispute, the branch association may be asked to undertake certain investigations, or the tribunal itself may take such steps as may be found necessary to secure such information desired. After investigation the tribunal is required to present to the branch council a report of facts found from the evidence placed before it, and a finding expressed in specified terms. The tribunal may consider and advise only on specific cases and cannot lay down general rules or principles with regard to fees in medical practice. Further, the tribunal cannot be called on to determine questions of policy with regard to medical fees.

Vitamin Content of Mutton Bird Oil

For several years mutton bird oil (from the local petrel *Puffinus tenuirostris*) has been sold in Victoria and other parts of Australia for the same purpose as cod liver oil. The oil is obtained from the stomach of the young bird at the end of the nesting season and it has been regarded as a reliable source of vitamin A. The original estimations, however, were carried out by biologic methods in the early days of vitamin A estimation before the modern methods were perfected. The vitamin A content of various specimens of the oil has recently been estimated by Davies in Melbourne by nonbiologic methods, namely the Carr-Price process, in which the Lovibond tintometer is employed to estimate the intensity of the blue color in the nonsaponifiable fraction, and the measurement of the intensity of absorption at 328 millimicrons of a solution in cyclohexane. Estimations have been made with both commercial and fresh noncommercial samples and it appears that the A content of the oil is of the very low order of 0.005 per cent (4 blue units) and therefore virtually useless as a medicinal source of vitamin A, even before it has been subjected to the commercial refining processes, which destroy the vitamin. It has also been shown that the liver oils of common local fish such as the snapper, shark, barracuda and mullet, usually contain from 100 to 800 times the concentration in mutton bird oil. The oil was assayed also for vitamin D by the prophylactic biologic method of Hume, Pickersgill and Gaffikin (1932), on albino rats. It is reported to contain "the very low value of 5 international units per gram" and therefore cannot be compared with cod or halibut oil as a vehicle for vitamin D. Finally it has been pointed out that the oil is of little use as a food, as it is mainly a liquid wax rather than a true fat. In view of these facts it would appear better to exploit the common fish liver oils as a vehicle for vitamin A than to continue the use of mutton bird oil.

A Bureau for the Translation of Foreign Literature

A bureau has been opened in Sydney for the translation into English of foreign scientific literature. The staff consists of five professional men from Vienna, where they were previously connected with such an enterprise. The work of this bureau, known as the Scientific Research Auxiliary Services, should prove valuable to research workers in this country, where expert linguists with some scientific experience are rare.

The Surgical Treatment of Angina Pectoris

Dr. Daniel Danielopolu, a professor at the University of Bucharest, in a recent lecture in Berlin stated that some physicians believe that the scope of the surgical treatment of angina pectoris is to relieve the pain. We would do a disservice to patients if we stopped the pain which befalls them while walking, as it is a signal calling their attention to the approaching attack, whereupon they halt and their hearts get some rest. The object of the operative treatment is the prevention of an attack. What is the mechanism of prevention? Obviously not the removal of the pathologic condition of the coronary arteries nor the stoppage of pathologic changes in the cardio-aortic plexus, because these are not reversible. Danielopolu has shown that these changes are only a predisposing factor and that at the moment of attack something else occurs. Disturbance of the equilibrium between the work and the blood supply of the heart muscle ensues as a result of the accumulation of toxic products of fatigue and these stimulate the sensory nerve endings. This excitation produces, by way of the bulb of the spinal cord, what Danielopolu calls the pressor reflex, which gives rise to certain symptoms and aggravates the intoxication produced by the products of fatigue.

When Danielopolu started his investigations he sought to eliminate this nervous mechanism, the so-called pressor reflex, by somehow interrupting this reflex nerve path. In Danielopolu's method great stress is laid on cutting the more centripetal fibers. In his method the bilateral cutting of the vagus is superfluous, and removal of the stellate ganglion is not permissible because through this ganglion, besides centripetal fibers, sympathetic fibers and coronary dilating fibers pass. Thanks to clinical and experimental research it is known what the role of every nerve is and on this ground Danielopolu recommends the following procedure: cervical sympathectomy without removing the stellate ganglion; cutting of the communicant branches of the vertebral nerve (sixth cervical to first dorsal) and that of the perpendicular vagus ramifications. Of course, before operating one must try medical treatment, but whenever improvement has been thus attained the operation is indicated unconditionally, because a later fatal attack cannot be excluded. With regard to anesthesia, Danielopolu suggests general narcosis. A patient with angina should not know about the details and phases of the operation being performed on him. The operation can be performed in one or two sittings. At the first sitting the dissection of the communicant branches of the vertebral nerve and in the second the cervical sympathectomy is performed. In Danielopolu's cases the first part of the operation often sufficed. Shortening the time of operation reduces the risk of shock.

The Regulation of Balneologists

Under the presidency of Dr. George Baltaceanu, professor of balneology and dietetics at the University of Bucharest, the Supreme Balneoclimatic Council resolved to regulate the number of physicians practicing at bathing resorts. For the younger generation, two or three positions will be allowed according to the importance and size of the bath. It has

been resolved that the ministry of public health shall appoint four official balneologists who will superintend the therapeutic possibilities in the single bathing resorts. These, according to their importance, will be distributed in categories. Those in the first category will receive a government subsidy and will be equipped with the most modern therapeutic appliances. The council will take steps at every bath resort to establish a dietary department. The ministry of health will provide cooks, who will be trained at the dietetic clinic of Bucharest University. Provisions are being made that during the bathing season from June 1 till September 30 patients and visitors traveling to health resorts will be given 50 per cent reduction in the railway fare. The ministry of health will reduce the number of first class balneoclimatic stations from 170 to twenty-six. The directors of balneoclimatic stations must be university graduates.

Medical Conditions in Bulgaria

Sofia University, which this year celebrates its fiftieth anniversary, has had a faculty of medicine only since 1918. The average number of physicians who settled in Bulgaria between 1921 and 1937 was 108. At present there are 2,900 medical practitioners in Bulgaria, the ratio to the population being 1:2,200, the rate having been 1:5,090 in 1924. There is a plethora of doctors in the greater cities, while in the villages there is a shortage. The decrease in the number of physicians in the later years is due to the lack of foreign currency, which renders studying abroad almost impossible, while the faculty of medicine at Sofia admits students only in a limited number. There are 1,100 dental surgeons, all of whom have foreign, chiefly German, diplomas. Dental technicians are not allowed to carry on dental practice in Bulgaria; still there are quacks. About twenty years ago the dental school was dissolved. The number of midwives is 900. There are 382 state-paid midwives in the villages. Hospital nurses are being trained at the Red Cross Hospital in Sofia. The period of training is three years. Their preliminary education generally is restricted to the secondary school.

Marriages

ROBERT HAMILTON WILLIAMS, Olympia, Wash., to Miss Frances Seward Anderson of Lynchburg, Va., June 17.

GEORGE SELLERS GRAHAM, Birmingham, Ala., to DR. SARAH HENRIETTA MCCARTY of Edinburgh, Scotland, July 12.

CLAUDIO RODRIGUEZ ARCE, Newport News, Va., to Miss Louise Henrietta Berger of Richmond, June 14.

CHARLES BURDIS DAVIS JR. to Miss Margaret MacRae Williams, both of Wilmington, N. C., July 15.

SAMUEL OLIVER CANTEY JR. to Miss Elizabeth Yates Simons, both of Charleston, S. C., June 14.

NICHOLAS E. DOBOS, San Antonio, Texas, to Miss June R. McConnell at Greensburg, Ind., June 1.

LAWRENCE E. KELSEY, Kewanna, Ind., to Miss Loretta Lucille Cooney of South Bend, June 2.

DAVID WILLIAM MARTIN, Durham, N. C., to Miss Joanna Ward Law of Austin, Texas, June 23.

PERCY RYLAND FOX, McComas, W. Va., to Miss Nina Cornelia Kelly of Bristol, Va., August 5.

ALBERT I. DU VALL, Marlboro, N. J., to Miss Jean Anderson McCrae of Haddonfield, June 17.

ABRAM JACK TANNENBAUM to Miss Leah Louise Baach, both of Greensboro, N. C., June 10.

DANIEL SUMNER ELLIS, Richmond, Va., to Miss Eloise Goodman of Newport News, June 24.

JEFFERSON DAVIS, Waxhaw, N. C., to Miss Frances Evelyn Little of Statesville, July 15.

ALBERT J. CREVELLO, Warren, Pa., to Miss Leocadia Krysiak of Shenandoah, January 22.

JOHN D. HAMNER JR. to Miss Evelyn Shepherd, both of Richmond, Va., June 24.

Deaths

Francis Hoeffler McMechan, Rocky River, Ohio; Medical College of Ohio, Cincinnati, 1903; member of the American Society of Anesthetists and the American Society of Regional Anesthesia; honorary member of the Royal Society of Medicine Section on Anesthetics, Société française d'anesthésie et d'analgésie, Sociedad de anestésistas de México, Società italiana di anestesia e di analgesia, Australian Association of Anesthesia, Association of Anesthesia of Great Britain and Ireland and others; secretary-general of the Associated Anesthetists of the United States and Canada, and of the International Anesthesia Research Society; honorary associate editor of the *British Journal of Anesthesia* and editor of *Current Researches in Anesthesia and Analgesia*; editor of the *Quarterly Supplement of Anesthesia and Analgesia*, *American Journal of Surgery*, 1914-1926; editor of the *Ohio State Medical Journal*, 1919-1923; anesthetist to St. Mary's Hospital, Cincinnati, 1903-1914; aged 60; died, June 29, of arthritis deformans, arteriosclerosis and myocarditis.

Hoyt E. Dearholt • Milwaukee; Rush Medical College, Chicago, 1900; past president of the State Medical Society of Wisconsin and of the Milwaukee Academy of Medicine; vice chairman and secretary of the Wisconsin Committee, International Congress on Tuberculosis, 1907-1908; a director of the National Tuberculosis Association, the American Public Health Association, the National Child Welfare Association and the Wisconsin Conference on Social Work; one of the founders of the River Pines Sanatorium, Stevens Point, Wis., orthopedic surgeon to the Milwaukee County Hospital, 1905-1907, and the Milwaukee Children's Hospital, 1906-1910; chief of health instruction, Extension Division, University of Wisconsin, in 1913; one of the founders, formerly managing editor and for many years on the editorial board of the *Wisconsin Medical Journal*; since 1910 executive secretary of the Wisconsin Anti-Tuberculosis Association; aged 60; died, July 12, in the Columbia Hospital of multiple myeloma.

Warren Plimpton Lombard, Ann Arbor, Mich.; Harvard University Medical School, Boston, 1882; since 1923 emeritus professor, from 1892 to 1898 professor of physiology and histology and from 1898 to 1923 professor of physiology at the University of Michigan Medical School; assistant in physiology at Columbia University, New York, 1886-1888, and assistant professor of physiology at Clark University, Worcester, Mass., 1889-1892; past president and secretary and member of the executive council of the American Physiological Society; member of the Society for Experimental Biology and Medicine; corresponding member of the Société de biologie and associate member of the Société royale des sciences médicales et naturelles de Bruxelles; author of numerous articles in various technical journals; aged 84; died, July 13, in the University Hospital of mesenteric thrombosis.

Jacob Franklin Highsmith • Fayetteville, N. C.; Jefferson Medical College of Philadelphia, 1889; member of the House of Delegates of the American Medical Association, 1907-1909, 1912, 1921 and 1922; past president of the Medical Society of the State of North Carolina, the Cumberland County Medical Society and the Tri-State Medical Association of the Carolinas and Virginia; past president of the North Carolina Hospital Association; past president of the state board of medical examiners; fellow of the American College of Surgeons; served as chairman of the medical advisory board during the World War; medical director and superintendent of a hospital bearing his name; aged 70; died, June 22, of cerebral and coronary embolism.

Albert Mathieu • Portland, Ore.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1905; associate clinical professor of obstetrics and gynecology at the University of Oregon Medical School; member and past president of the Pacific Coast Society of Obstetrics and Gynecology; one of the founders and past president of the Portland Society of Obstetricians and Gynecologists; fellow of the American College of Surgeons; member of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons; on the staffs of the Multnomah County Hospital and St. Vincent's Hospital; aged 57; died, July 4, of coronary thrombosis.

Hans Martin Finnerud, Watertown, S. D.; Hahnemann Medical College and Hospital, Chicago, 1889; member of the South Dakota State Medical Association; vice president and medical director of the Midland National Life Insurance Company; formerly member of the state board of regents of education; member of the board of education of the city public schools, state senator, and member of the state board of chari-

ties and corrections; was a member of the state board of exemptions during the World War; aged 80; formerly on the staff of the Luther Hospital, where he died, July 10.

Oliver William Hill • Knoxville, Tenn.; University of Tennessee Medical Department, Nashville, 1907; past president of the Knox County Medical Society, the East Tennessee Medical Society and the Tennessee Pediatric Society; member of the American Academy of Pediatrics; on the staffs of the Fort Sanders Hospital, Knoxville General Hospital and St. Mary's Hospital; since 1915 lecturer at the Southern Pediatric Seminar, Saluda, N. C.; aged 56; died, June 21, of coronary occlusion.

Albert Haeseler Super, Pottstown, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1903; member of the Medical Society of the State of Pennsylvania and of the American Psychiatric Association; at various times on the staffs of the Allentown (Pa.) State Hospital, Pottstown Hospital and the Homeopathic Hospital; for many years superintendent of the Pennhurst (Pa.) State School; aged 58; died, May 11, of cerebral hemorrhage.

Henry Augustus Becker • Cleveland; Western Reserve University Medical Department, Cleveland, 1894; fellow of the American College of Surgeons; veteran of the Spanish-American War; served in various capacities on the staffs of the Fairview Park Hospital, Lakeside Hospital and the Cleveland City Hospital; formerly demonstrator of surgery, instructor in surgery and assistant clinical professor of surgery at his alma mater; aged 69; died, June 18.

Floyd Jackson Bolend, Oklahoma City; St. Louis College of Physicians and Surgeons, 1906; associate professor of medicine emeritus at the University of Oklahoma School of Medicine; on the staffs of the University Hospital, Oklahoma General Hospital and St. Anthony Hospital; served during the World War; aged 61; died, June 22, of coronary thrombosis.

Walden M. Ward, North Collins, N. Y.; University of Buffalo School of Medicine, 1885; past president of the Medical Society of the County of Erie; for many years health officer; was attending physician at the Thomas Indian School and government physician to Indians on the Cattaraugus Reservation; aged 80; died, May 5, of diabetes mellitus.

Thomas Henry Weldon, Manchester, Conn.; University of the City of New York Medical Department, 1883; member of the Connecticut State Medical Society; past president of the Hartford County Medical Society; on the staff of the Manchester Memorial Hospital; aged 77; died, May 21, of hypertrophy of the prostate and subacute prostatitis.

Linnaeus Hodgson Prince, Hines, Ill.; Jefferson Medical College of Philadelphia, 1900; member of the American Association of Pathologists and Bacteriologists; served during the World War; served as pathologist on the staff of the Veterans Administration Facility, where he died, July 8, of arteriosclerosis and cerebral hemorrhage.

William Frederick Lunsford • Kansas City, Kan.; University of Oklahoma School of Medicine, Oklahoma City, 1923; city health officer; formerly member of the state board of health of Missouri; aged 41; died, July 4, in a hospital at Nevada, Mo., of injuries received in an automobile accident.

Ulysses Grant Williams • Newport, N. Y.; Syracuse University College of Medicine, 1892; past president of the Herkimer County Medical Society; formerly coroner and for many years health officer in the Newport district; aged 76; died, May 14, in St. Luke's Hospital, Utica, of pneumonia.

George Nathan Wassom • Oelwein, Iowa; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1907; past president of the Fayette County Medical Society; formerly on the staff of the Mercy Hospital; aged 58; died, May 8, of coronary occlusion.

Ernest Herman Smith, Redding, Conn.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1889; member of the Connecticut State Medical Society; formerly member of the school board; aged 75; died, May 4, in the Danbury (Conn.) Hospital of pneumonia.

Samuel James Stewart, Alhambra, Calif.; Lincoln (Neb.) Medical College of Coter University, 1902; served during the World War; district health officer; formerly medical superintendent of the Nebraska Institute for Feeble Minded, Beatrice; aged 59; died, May 24, in the Alhambra Hospital.

Harold James Terrill • Ottawa, Kan.; University of Kansas School of Medicine, Kansas City, 1921; past president of the Franklin County Medical Society; on the staff of the Ransom Memorial Hospital; aged 44; died, May 19, of bronchopneumonia and acute military tuberculosis.

Aart Van Westrienen, Kenosha, Wis.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1899;

member of the State Medical Society of Wisconsin; on the staff of the Kenosha Hospital; aged 70; died, May 30, of myocarditis and arteriosclerosis.

Lewis Whitaker Allen, Tenafly, N. J.; Cooper Medical College, San Francisco, 1896; New York Homeopathic Medical College and Hospital, New York, 1897; formerly on the staff of St. Luke's Hospital, San Francisco; aged 67; died, June 13, of coronary thrombosis.

Edward Harvey White, Stanhope, Iowa; State University of Iowa College of Medicine, Iowa City, 1906; veteran of the Spanish-American and World wars; aged 60; died, May 18, in the Veterans Administration Facility, Des Moines, of diabetes mellitus.

Frederick William James, Utica, N. Y.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1894; aged 68; died, May 21, of chronic nephritis, acute dilatation of the heart and chronic endocarditis.

Charles Alvin Yocom, Douglassville, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1885; served during the World War; aged 81; died, May 9, in the Veterans Administration Facility, Coatesville, of chronic myocarditis.

David Charles Munford, La Habra, Calif.; Kansas Medical College, Medical Department of Washburn College, Topeka, 1909; served during the World War; aged 59; died, May 29, of injuries received in an automobile accident.

Gustav Walter Zulauf, Pittsburgh; University and Bellevue Hospital Medical College, New York, 1912; served during the World War; aged 49; superintendent of the Allegheny General Hospital, where he died, May 8, of myeloma.

George Conrad Weiss, Mount Vernon, N. Y.; Bellevue Hospital Medical College, New York, 1882; past president of the city board of health and health officer; aged 78; died, May 31, in Poughkeepsie of coronary artery disease.

Paul F. Pershing, Altoona, Pa.; Jefferson Medical College of Philadelphia, 1910; member of the Medical Society of the State of Pennsylvania; on the staff of the Altoona Hospital; aged 52; died, May 2, of heart disease.

Percy Greenough Drake, Hartford, Conn.; Harvard University Medical School, Boston, 1904; member of the Connecticut State Medical Society; aged 62; died, May 22, of arteriosclerosis and cerebral thrombosis.

Ernest Alvah Brooks, Brooklyn; Long Island College Hospital, Brooklyn, 1932; member of the Medical Society of the State of New York; aged 29; died, June 9, in the Long Island College Hospital.

Nina Maximova Take, New York; Medical Institute for Women, St. Petersburg, Russia, 1913; aged 49; died, May 30, in the Harlem Valley State Hospital, Wingdale, N. Y., of pulmonary tuberculosis.

Frank H. Widman, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1893; registrar and professor of physiology at his alma mater; aged 67; died, May 7, of cerebral thrombosis.

Eugene Orvin Barker, Guthrie, Okla.; Northwestern Medical College, St. Joseph, Mo., 1883; member of the Oklahoma State Medical Association; aged 84; died, June 24, of coronary thrombosis.

Albert Lake Tuttle, Lakeville, Conn.; Albany (N. Y.) Medical College, 1888; member of the Connecticut State Medical Society; aged 75; died, May 11, of arteriosclerosis and cerebral thrombosis.

Peter Prentiss Causey, Courtland, Va.; University of Maryland School of Medicine, Baltimore, 1897; member of the Medical Society of Virginia; county health officer; aged 66; died, June 5.

Columbus C. Ward, Crisfield, Md.; Baltimore Medical College, 1894; formerly county health officer; aged 74; died, May 26, in the University Hospital, Baltimore, of carcinoma of the pancreas.

James Jackson Backus, Gracey, Ky.; Chicago Homeopathic Medical College, 1886; member of the Kentucky State Medical Association; aged 82; died, June 23, of coronary thrombosis.

Bernard Francis Corbett, Flint, Mich.; Marquette University School of Medicine, Milwaukee, 1913; served during the World War; aged 50; died suddenly, June 29, of heart disease.

Arthur Keys Odbert, South Brownsville, Pa.; University of Pittsburgh School of Medicine, 1911; aged 51; died, May 7, in the Charlevoix-Monessen Hospital, Lock No. 4, of pneumonia.

Orland Vernon Donaldson, Gore, Ohio; Starling Medical College, Columbus, 1901; member of the Ohio State Medical Association; aged 60; died, June 23, of chronic nephritis.

William Louis Wheeler, New York; Columbia University College of Physicians and Surgeons, New York, 1900; aged 65; died, May 22, of carcinoma of the prostate.

Emma C. Lefevre, Elmira, N. Y.; University of Buffalo School of Medicine, 1892; aged 81; died, May 1, in the Arnot-Ogden Memorial Hospital of arteriosclerosis.

William J. Smith, Anderson, S. C.; Medical College of the State of South Carolina, Charleston, 1903; aged 60; died, May 22, in the Anderson County Hospital.

Howardson Nathaniel Stoute ☉ New York; University and Bellevue Hospital Medical College, New York, 1924; aged 46; died, May 9, of malignant hypertension.

William H. Balthrop, Nashville, Tenn.; Vanderbilt University School of Medicine, Nashville, Tenn., 1882; aged 84; died, June 24, of cerebral hemorrhage.

Franklin Endress Bamberger, Lebanon, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1902; aged 73; died, May 22, of chronic myocarditis.

William Muthard Hillegas, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1894; aged 65; died, May 11, of chronic myocarditis.

Joseph William Ballenger, Carbon Hill, Ala.; Vanderbilt University School of Medicine, Nashville, Tenn., 1884; aged 78; died, June 3, of mitral stenosis.

Hosea Franklin Downs, Clanton, Ala.; University of Nashville (Tenn.) Medical Department, 1908; aged 50; died, May 9, of pulmonary tuberculosis.

William Fairbanks, Buffalo; Bellevue Hospital Medical College, New York, 1891; aged 69; died, May 6, of arteriosclerosis and chronic myocarditis.

Arthur N. House, Kankakee, Ill.; Rush Medical College, Chicago, 1893; aged 72; died, May 12, near Escalon, Calif., of arteriosclerosis and heart disease.

Isaac H. Springer, Daytona Beach, Fla.; University of Georgia Medical Department, Augusta, 1875; aged 85; died, May 31, of cerebral hemorrhage.

James Sterrett Caldwell, Cincinnati; Miami Medical College, Cincinnati, 1883; aged 88; died, June 14, of ventricular fibrillation and bronchiectasis.

George Alvin Clauser, Bridgewater, S. D.; State University of Iowa College of Medicine, Iowa City, 1897; aged 74; died, June 27, of carcinoma.

Edward Engler Gibbons, Baltimore; University of Maryland School of Medicine, Baltimore, 1895; aged 67; died, May 30, of acute myocarditis.

Francis Edwin Van der Veer, Atlanta, Ga.; Albany (N. Y.) Medical College, 1899; aged 66; died, May 30, of cerebral hemorrhage.

Otho Barnett, New Harmony, Ind.; University of Louisville (Ky.) Medical Department, 1894; aged 70; died, June 26, of angina pectoris.

John L. Seay, Eastwood, Ky.; Louisville Medical College, 1889; aged 71; died, May 29, of injuries received when struck by an automobile.

John Franklin Rice, Vinita, Okla.; Missouri Medical College, St. Louis, 1886; aged 79; died, May 23, of cerebral arteriosclerosis.

Daniel Lafayette Carmichael Sr., Los Angeles; Jefferson Medical College of Philadelphia, 1884; aged 81; died, May 16, of myocarditis.

Claude Gailard Martin, Joplin, Mo.; Hospital College of Medicine, Louisville, 1907; aged 56; died, May 22, of coronary heart disease.

Ernest M. Thompson, Fayetteville, Ark. (licensed in Oklahoma, under the Act of 1908); aged 68; died, May 28, of chronic myocarditis.

Ferdinand H. Scholle, Los Angeles; Baltimore University School of Medicine, 1897; aged 58; died, May 19, of cirrhosis of the liver.

Edward C. Bechtol, Grapevine, Texas; Dallas (Texas) Medical College, 1904; aged 79; died, June 20, of cerebral thrombosis.

Conrad Peter Brunig, Lehigh, Kan.; Kansas City (Mo.) Medical College, 1903; aged 68; died, May 8, of carcinoma of the larynx.

Feodor W. Koehler, Louisville, Ky.; Hospital College of Medicine, Louisville, 1881; aged 82; died, May 30, of coronary occlusion.

Logan R. Pryor, Eaton, Ohio; Pulte Medical College, Cincinnati, 1896; aged 66; died, May 14, of cerebral thrombosis.

Bureau of Investigation

AN "EPILEPSY CURE" FRAUD

Anli Company Is Debarred from the Mails

Under the trade style of the Anli Company a Mr. and Mrs. Murray A. Shaw and a Mr. and Mrs. Benjamin Margolis of New York City sold through the mails a nostrum called the "Black and White Treatment" for epilepsy. Hon. W. E. Kelly, Acting Solicitor for the Post Office Department, in recommending the issuance of a fraud order against this scheme, brought out the following facts:

The business was started in August 1937 and the public was reached through advertisements placed in various newspapers and magazines. Those who answered them received a long form-letter, claiming among other things that:

"Of the hundreds of poor afflicted sufferers we have treated, only six per cent have not gotten complete relief, and every one of these have immediately received their money by return mail when they requested.

"Epilepsy in its most dreadful forms has at last been overcome. Up to a few years ago, the entire medical profession could accomplish very little with this awful disease.

"Take our treatment and become our life-long friend. The results you will get in the first few days will bear out this important fact. If you suffer from epilepsy, St. Vitus dance, hysteria, convulsions, falling sickness, you will get complete relief."

In its written "guaranty" the company declared that its treatment contained "no poisons of any kind" or "habit-forming drugs," and "will not harm man, woman or child." Further,

FITS (EPILEPSY) ANLI CO.	stopped at once or no pay. Results guaranteed. Write at once for FREE literature, on "Black and White" Treatment.	DF1.8 220 W. 42nd St., N. Y. C.
---------------------------------------	--	---

this "patent medicine" concern would mislead the public into believing that the nostrum had received scientific recognition, in making the following statement:

"THE NEW REMEDY"

"Recently the greatest specialists in epilepsy began their experiments on the thousands of patients in epilepsy colonies. Soon thereafter the following amazing report was officially issued: 'It is the most useful thing that has been learned since 1915 in the treatment of epilepsy. In 80 per cent of the cases tried at the North Carolina State Colony for Epileptics, it removed all attacks completely. It gives the best results and the least trouble of all remedies in the treatment of epilepsy.' We then at once decided to place this wonderful remedy within the reach of every suffering epileptic in this country and abroad. Our success was immediate and astounding."

Thus the concern would have the public believe that its "cure" was a new one, whereas the potent drug in it was phenobarbital (luminal), which was introduced to the medical profession for the treatment of epilepsy as long ago as 1912. The black tablets in the treatment were reported by government chemists to consist of sucrose, starch, blue dye and 0.63 grain of phenobarbital each; the white tablets were found to contain sucrose, starch, talc and 0.70 grain of phenobarbital each. The report pointed out that the patient who followed the directions would ingest about 4 grains (0.25 Gm.) of phenobarbital during the first two days. On succeeding days the amount of this drug would be gradually reduced until the tenth day, when he would be taking a little more than 1 grain (0.065 Gm.) of phenobarbital.

The Post Office Department presented medical evidence to show that phenobarbital can partially suppress convulsant symptoms due to excessive excitant stimuli to the motor mechanism of the brain but that these effects are merely temporary, since the drug does not remove the cause of epileptic or other convulsive fits or attacks; that it is not recognized as having the facility to "stop completely" all epileptic attacks in persons suffering from that disease as claimed by the Anli people, nor could they honestly represent that 94 per cent of all epilepsy victims would be cured of that disease by the product in question. It was further pointed out that in many instances the causes of epilepsy cannot be determined even by careful and complete physical examination, as in some cases the condition might be due to brain injury, which might require an operation, and in these circumstances neither the Anli treatment nor any

other medication would be of any use. It was shown too that, regardless of the time that victims of epilepsy take the barbiturates or other sedative drugs they cannot be assured of "complete relief" from the disease by such means.

Although the Anli concern claimed that its treatment contained no habit-forming drugs, the Post Office report pointed out that this claim was false, as phenobarbital is definitely recognized as a potent harmful narcotic, which is habit forming; that many cities, states and countries permit that it be sold only on a physician's prescription. Also declared false was the claim that the Anli treatment contains a "new remedy," since its constituent drug was known and introduced in 1912.

The Post Office Department pointed out that by means of fraudulent representations the Anli concern was able to charge \$5 for sixty tablets containing an amount of phenobarbital that could be bought at a drugstore for \$1 and, further, that the "guaranty" of a refund in thirty days to dissatisfied customers was practically meaningless, as the company attempted to persuade them to continue taking the treatment longer. Further, it was shown that no physicians, chemists or pharmacists were employed by the concern, which simply purchased the tablets from a New York drug house. The fraud order debarring the Anli outfit from further use of the mails was issued Oct. 29, 1938.

A FRAUDULENT "CURE-ALL"

Harry Treats Swindle Is Denied Use of the Mails

Harry Treats Company was the name used by a Harry Seligman of Philadelphia who conducted a fraudulent mail-order business, promoting a nostrum called "Special 'D' Herbal Tonic." This was represented to overcome kidney, bladder, gallbladder and heart disorders, "blood impurities," "body infections" and some other things.

Seligman's advertising listed a long series of symptoms that were supposed to indicate the need of taking his product and made it appear to be something of a cure-all. Analysis by government chemists showed it to be a mixture of magnesium carbonate, aloin, papain, baking soda, potassium bromide, bismuth subcarbonate, kaolin, glycerin, cudbear, orange syrup, tinctures of belladonna and nux vomica, and oils of peppermint, fennel and caraway, plus alcohol and water.

When the Post Office Department summoned Seligman to show cause why a fraud order should not be issued against him, expert medical testimony was brought in to show that the numerous disorders for which Seligman's nostrum was advertised may be due to a wide variety of causes, including venereal diseases, streptococcal infection and numerous others, the nature of which must be determined in each case by careful diagnosis and subjected to treatment to suit the individual case. It was further shown that the nostrum possessed only mild, antacid, laxative, diuretic and stomachic properties and hence was without substantial therapeutic value for any of the conditions for which it was sold. It was further pointed out that the use of the Seligman product might result in loss of life, because of the users' failure to obtain proper treatment for their maladies until they have become incurable.

Seligman's answer to the charges was that he had not represented his preparation as "overcoming" the various diseases and conditions named in the memorandum of charges. The Post Office, on the contrary, substantiated its charges by referring directly to the advertisements in which the diseases in question were mentioned. Seligman also claimed that he had discontinued all advertising, but the Post Office presented evidence showing that as of a recent date mail was still being received in connection with the enterprise. It was therefore recommended that a fraud order be issued and on Oct. 1, 1938, this was done, prohibiting the Harry Treats Company and its officers and agents as such from the further use of the mails.

In this connection it may be worth noting that in 1937 the Federal Trade Commission announced that, as the result of an action it had brought against Harry Seligman, trading as Harry Treats Company, Philadelphia, he had promised to discontinue representing that his product "R 1739" is a competent treatment for diseases of the kidneys or bladder, and that his "Special 'D' Herbal Tonic" is an effective remedy for sores, eczema or nervous excitement. Further, he promised to discontinue advertising that he conducts a medical clinic.

Correspondence

THE DEGREE OF DOCTOR

To the Editor:—I am a member of that most insignificant class of human beings which in the technical language of the medical profession is known as "the laity." Whatever meager medical knowledge I may have absorbed from a course in a nonapproved evening medical school some thirty years ago has long ago faded into oblivion, leaving me only a rather unusual understanding of the place of medicine in the modern social order. As a layman I am interested in some of the problems of medical economics as far as they relate to providing adequate and scientific medical service to the public (protecting the public from quacks and impostors) and as certain threats to the medical profession threaten equally my own vested interests. As a doctor of philosophy I am very much alarmed by a recent tendency to lower the dignity of and public respect for not only the degree of doctor of medicine but also all other legitimate and earned doctorates.

Although both the federal and state laws are quite rigid in protecting the public against misbranded merchandise, not only medicines and foods but also other commodities, apparently the Better Business Bureaus and the Federal Trade Commission are entirely neglecting to protect the public against imposition and fraud on the part of those who by assuming the title of "doctor" give the impression that they are medically trained.

I recently submitted an advertisement of an optometrist describing himself as "Dr. Blank, O.D." to fifty persons of average intelligence. Forty-seven of these were definitely of the opinion that "Dr." Blank was a regular medical graduate who had by means of graduate work and other special training equipped himself to be especially well fitted to treat defects of the eye. A recent investigation has disclosed that practically all the "doctors" of optometry who constantly keep themselves before the public have had less than one year of college work. Many prominent officials of the optometric societies and state boards acquired their "knowledge" by means of six weeks residence or short correspondence courses. At the present time optometric education may be divided into two distinct types of institutions. The first type includes Columbia, Ohio State and California universities. These offer a standard four years course, based on a high school training, which course leads to the degree of B.S. or B.A. Neither of these standard institutions recognizes the "doctorate" in optometry either by granting the degree or by indicating that the degree is held by a member of the faculty. On the other hand, the second type of schools, privately owned and actually conducted for profit (although frequently chartered "not for profit"), grants the doctorate on less work than is required for graduation from a good junior college. An official of one of the Chicago optometric colleges recently boasted that the Chicago schools receive a good many students from California because they give the "doctorate" degree while their own state university grants merely a bachelor's degree. In other words, the low standards of these private schools clearly stamp them as diploma mills. What I have stated concerning optometry can with equal truth be said about the schools of chiropody. I see a distinct danger that all the excellent work which has been done by the American Medical Association to weed out the inferior medical schools will be undone if the present tendency in the direction of optometry and chiropody is permitted to continue. These schools are now beginning to offer four year courses which embrace practically all the subjects in the regular medical curriculum. The actual facilities and faculty of some of these schools would have been a disgrace even to the old National Medical University and the St. Louis College

of Physicians and Surgeons. Their present plans appear to be, according to reliable information, to convert these schools into medical schools granting the M.D. degree, first by calling it "M.D. in Optometry" or "M.D. in Chiropody" and then making it a straight M.D. By offering a four year course having, on paper, the content of a regular medical course, it will not be difficult for them to induce a politically minded legislature to give their graduates full M.D. recognition.

Although I desire merely to direct your attention to a situation which, even from a layman's standpoint, constitutes a menace to the public health, it may not be out of place to mention several possible remedies. The corporation laws of Illinois and other states should be amended so as to prevent the granting of a doctor's degree by any educational institution on less than seven years of actual work. The statutes should prohibit the use of the title doctor in connection with any healing art by any one who does not have a regular medical training. The statutes that grant special privileges to persons selling eye glasses, known as optometrists, should be repealed and the sale of eye glasses, like the sale of shoes, trusses and braces, should be open to all merchants.

There does not appear to be any more reason why the correspondence school trained, or the six weeks course, optometrist or chiropodist (or even the four year men in these fields) should be called "doctor" than that the same degree should be granted to graduate nurses or to barbers or beauty culturists. It is probably only a question of time until some bright mind will conceive the idea of purchasing from the state of Illinois a charter for a college of barbering and beauty culture and of granting a "doctorate" to its graduates. That such a plan would be quite profitable seems certain. The barbers would have in their favor, at least, some historical basis. The various functions of the beauty culturist, such as massage, application of electricity to the hair and face, the puncturing and squeezing of pimples and extraction of blackheads, certainly is as much "doctoring" as removing corns, extracting ingrown toe nails and massaging fallen arches.

It may be well for the American Medical Association to work with such groups as the American Association of University Professors, the American Association for the Advancement of Science and other bodies to secure legislation to protect the public against fraud and deception and to prevent the unscrupulous charlatans from appropriating to themselves prestige and glory which the medical profession has earned by years of sacrifice, suffering, endless labor and unselfish faithful service to humanity.

FREDERICK JUCHOFF, LL.M., Ph.D., Chicago.

CARBOHYDRATES AS CONSTITUENTS OF PROTEINS

To the Editor:—A short editorial in the May 20 issue of THE JOURNAL under the heading "Carbohydrates as Constituents of Proteins" contains a reference to the work of Claude Bernard. According to this, Bernard, finding that liver glycogen is formed when protein is fed to an animal, assumed that preformed carbohydrate must be present in the protein and postulated a glucosidic theory of protein structure.

As I have pointed out in a recent paper (Claude Bernard and the Theory of the Glycogenic Function of the Liver, *Ann. Sc. 2:47, 1937*), widespread misapprehension exists today concerning Bernard's views on glycogen formation in the liver. As a result of his early discoveries, this great French physiologist was deeply impressed with the idea that glycogen and dextrose are secretions of the liver; according to this idea, a continuous formation of sugar accounted for the presence of this substance in the liver of a fasting animal or of an animal receiving a noncarbohydrate diet: "Le sucre hépatique est formé primitivement dans le foie," (Claude Bernard, 1853).

Although he believed that protein could be converted into liver glycogen, Claude Bernard doubted the possibility that a direct transformation of ingested sugar into glycogen in the liver could occur. This point is discussed at some length in my paper just referred to, in which a number of Bernard's mutually contradictory statements on this subject are quoted. It must be stressed that the formation of sugar in the liver of the fasting animal, necessitating the production of sugar from noncarbohydrate sources including protein, is a fundamental element in Claude Bernard's theory of the glycogenic function of the liver.

The discovery that some types of protein matter contain sugar was not made by Claude Bernard; indeed, the presence of sugar in protein matter such as egg white was known many years before the discovery of glycogen. Realization of the possible metabolic significance of the preformed carbohydrate in protein was due to Frederick Pavy, an ardent opponent of Claude Bernard's theories. Pavy's own investigations and his theory of the "glucoside constitution of proteid matter" (1881, 1893) greatly assisted Pflüger's opposition to the belief that liver glycogen can be formed from protein per se (Pflüger, E. F. W.: *Das Glykogen*, 1905), an opposition which Pflüger was ultimately forced to withdraw. Nevertheless, the erroneous idea of Pavy and Pflüger is now ascribed to Claude Bernard, whose method of publication in discursive "leçons" has unfortunately assisted in bringing about the present confusion.

Hampstead, London, N. W.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

BREAST VERSUS BOTTLE FED INFANTS

To the Editor:—A recent speaker is quoted in one of our local papers as follows: "The children fed mother's milk grow up with better muscles, teeth and bones and have a better chance of surviving the first six months of life than those fed on cow's milk." These assertions are, no doubt, of the sort one should like to accept as "self evident." It strikes me, however, that much loose thinking and even more loose talking has been done on this subject. I should greatly appreciate your comment on the following questions: 1. Of statistics intended to show the superiority of breast fed over bottle fed babies, how many are based on carefully controlled observations covering comparable groups of children in which the only variable is the feeding? 2. Is there any series of observations covering infants in the so-called favored class with reference to results of breast and bottle feeding? 3. It would be easy to believe that bottle fed babies in the slums would be much more subject to gastrointestinal disturbances than would breast fed babies in the same group. In how many cases does this explain the apparent superiority of breast feeding over bottle feeding? 4. If well baby clinics urge breast feeding rather than bottle feeding and if one allows that mothers attending these clinics are likely to be those most diligent in the general care of the child, is it not possible that we have here an artificial selection which would tend toward favorable statistics for breast feeding when, as a matter of fact, many other factors may be concerned in the favorable result? 5. Is it not true that even in the course of the past ten years the practice in artificial feeding has changed to such an extent as partially or wholly to vitiate the older statistics? It is my personal feeling that nowadays it is rare to encounter an infant with gastrointestinal difficulties which do not yield promptly to feeding based on modern practice. 6. In the quotation given at the beginning of this letter it would be interesting to know just what criteria were used in deciding on the following points: (a) "better muscles," (b) "better teeth," (c) "better bones." Here again may we not have an example of the sort of loose talk that sounds well but may be difficult or impossible to substantiate?

Thomas C. McVeagh, M.D., Honolulu, Hawaii.

ANSWER.—Brennemann (Practice of Pediatrics, Hagerstown, Md., W. F. Prior Company, 1936, vol. 1, chapter 25) states: "The milk of every mammal is specific for its young. To this man is no exception. There is, furthermore, evidence that

the milk of one mammal is not only imperfectly adapted to the young of other mammals but that there is even something harmful in nonspecific milk. The essential nature of this specificity is unknown. While it may eventually prove to be largely, or wholly, a matter of chemistry, there is reason to believe that there is also an intangible biologic factor. . . . That an apparently perfect nutritional result can be obtained without any breast milk is a matter of daily observation. That the apparent result may not be real is possible, even probable."

1. The best statistics on the superiority of breast feeding are those of Grulee, Sanford and their co-workers (*THE JOURNAL*, Sept. 8, 1934, p. 735, and June 1, 1936, p. 1986; *J. Pediat.* 6:825 [June] 1935, and 9:223 [Aug.] 1936). These are carefully controlled observations covering comparable groups of infants in which the only variable was the feeding. They observed more than 20,000 infants from birth to 9 months of age attending the stations of the Infant Welfare Society of Chicago over a period from 1924 through 1929. Of these, 48.5 per cent were breast fed, 43 per cent were partially breast fed and 8.5 per cent were artificially fed. These infants lived in an environment in which they were particularly subjected to the chance of infection. Gastrointestinal, respiratory and unclassified infections were tabulated. The seasonal curve of morbidity and mortality was not affected in its contour by the type of feeding. The height of the curve, however, was continually lowest in all seasons in the breast fed infant. All three types of infections listed were involved about equally. There was a definite rise in the morbidity after the sixth month in the artificially fed that was not shared in by either the breast fed or the partially breast fed group. The mortality figures were as follows: Of the total deaths 6.7 per cent occurred in the breast fed, 27.2 per cent in the partially breast fed and 66.1 per cent in the artificially fed. The total morbidity of the breast fed group was 37.4 per cent, of the partially breast fed 53.8 per cent and of the artificially fed 63.6 per cent. The charts show conclusively the effect on the mortality of infants and protection against infection. Also the general incidence of infantile eczema was lowest in the breast fed infants. In the partially breast fed it was twice as frequent as in the breast fed, and in the artificially fed infants it was seven times as great.

2. Blessing (The Incidence of Breast Feeding in a Suburban Metropolitan Area, *J. Pediat.* 10:792 [June] 1937) found, in accordance with the experience of most pediatricians dealing with an upper middle class private clientele (so-called favored class), that the incidence of breast feeding in this group was low. Yet the infants seemingly were healthy. Of course, he studied only 437 instances. At 1 month 24 per cent were completely weaned; at the end of three months only 19 per cent were completely breast fed, 25 per cent partially and 56 per cent completely weaned. At the end of six months, 83 per cent were completely weaned. He reviews the literature relating to the experience of others with this type of private practice. Most of the authors reviewed have statistical tables of results of breast and bottle feeding in private practice. He concludes that breast milk is the ideal infant food but agrees with Lamb, who states that "it is quite proper to encourage breast feedings, but we should not make the mistake of disparaging substitute feedings, for . . . the babies fed on artificial milk formulas have shown no serious deviation from that normal development that regularly follows adequate breast feedings," and with Glazier, who pointed out that infant mortality and morbidity are definitely related to economic and hygienic conditions and that in districts where these conditions were good the average bottle baby does as well as the breast fed. The converse is undoubtedly true, as shown so conclusively by Grulee's figures.

3. Refer above to Grulee and his associates' statistics.

4. The babies in the Grulee series are a pretty good cross section of those living in the slum districts of Chicago. All indigent families with newborn infants are followed up by the Chicago Health Department and almost forced to attend Infant Welfare Clinics.

5. This is a debatable point.

6. The "loose talk" mentioned probably has not been substantiated statistically but is merely some one's personal impression.

CONTAGIOUS DISEASE AND OBSTETRIC PRACTICE QUERIES AND MINOR NOTES

Jour. A. M. A.
Aug. 26, 1939

To the Editor:—As an adviser to several hospitals for the management of their maternity departments, I am confronted with several problems to which I do not know the correct answers or where to find their solution; hence I apply to you: In the management of an isolated maternity department within a general hospital, with separate isolation for infectious cases but having no detention hospital, what cases exposed to contagious diseases before entering the hospital, what disposition should be made of a woman in labor at whose home there is whooping cough, measles, mumps, scarlet fever, diphtheria or septic sore throat? Should such a patient be admitted to the maternity floor for delivery? Should she be kept in the lying-in room before delivery? Should she be kept in the general nursery? Should the nursery nurses take care of the infant in the maternity floor if her husband, who lives at home, be permitted to visit her at the hospital? Should a patient with lobar pneumonia be kept on the maternity floor if an acute infection of the upper respiratory tract be kept on the maternity floor? Should a patient in whom pyelitis develops be moved from the quarters with patients with puerperal infection? At first thought it would seem as though the answers to all these questions should be quite obvious. However, in justice to the patient and the newborn infant should the hospital refuse them admittance? I may add that my conferences with pediatricians and epidemiologists on the questions bring answers only such as "Carrying of contagion would be very remote" or "At such and such hospitals they do so and so," and that does not solve the problem. I believe that the problem is of sufficient importance to merit an authoritative statement for guidance. If there are in print hospital regulations covering these questions, I should appreciate being directed to them.

H. F. Beckman, M.D., Indianapolis.

ANSWER.—(This query has been referred to several qualified obstetricians and health officials.) The questions can be answered, with a few exceptions, most expeditiously by dividing the diseases about which inquiry is made into two groups. Group 1 would include whooping cough, measles and mumps. Group 2 would include scarlet fever, diphtheria and septic sore throat. The differences between these two groups are that the first group is confined largely to children and that their spread by intermediate carriers, if it occurs, has at least not been demonstrated. The second group may occur at any age and carrier transmission is either proved or strongly suspected. The first group can therefore be treated with more latitude. A pregnant woman coming from a home in which there is whooping cough, measles or mumps could properly be admitted to the maternity floor if she has previously had the disease and if she is bathed, shampooed and fitted with clean clothing before she enters the ward. She may also be delivered in the regular delivery room and kept with other parturient patients. The baby may be cared for by the regular nursing personnel. She may be kept in the general nursery and need not be kept in detention. Her husband may be permitted to visit her at the hospital, especially if the wearing of gowns and masks is the routine practice.

With a patient coming from a home in which there is scarlet fever, diphtheria or septic sore throat, the procedure should be different. Such a patient cannot be kept safely on the maternity floor, delivered in the regular delivery room or be under the care of regular nursing personnel who also care for other mothers and babies. The baby likewise should be kept separate, and no visitors should be permitted for their own sake. These precautions are advisable even if the woman herself has not been proved to be a carrier, since negative laboratory reports are not in themselves sufficient justification for possibly exposing other patients on the maternity floor or in the nursery to these serious carrier-transmitted contagious diseases.

A patient with lobar pneumonia or an acute infection of the upper respiratory tract should not be kept on the maternity floor. A patient with pyelitis need not be moved from the maternity floor provided isolation technic is followed. None of the patients referred to a hospital may be refused "in justice to the patient and the newborn infant," the general opinion is that home confinement under proper conditions has been demonstrated to be as successful and as safe as hospital delivery. The presence of scarlet fever and pregnancy in the same house constitutes a serious threat to the parturient woman owing to the close relationship of the streptococci responsible for scarlet fever and for puerperal infection. The parturient woman should be removed from contact with the scarlet fever patient as soon as possible, either by separating off a portion of the house or by arranging for her care in another house where there are no children. If she has previously had scarlet

fever, the danger is lessened as far as her likelihood of getting the disease is concerned, but she may still have acquired an implantation of streptococci in her throat from which she may become puerperally infected or from which her baby may derive scarlet fever or septic sore throat. Passive immunization may be given if no contraindications exist. Essentially the same argument applies to diphtheria. If the condition of the patient warrants and there are no contraindications such as previous immunization of antitoxin or a known allergic state, passive immunization should be given against diphtheria. Cultures should be taken of the nose and throat daily and appropriate local treatment given in an endeavor to eradicate the streptococci which may be present. In summation, it would appear that the same regulations regarding the spread of infectious and contagious diseases so far as they relate to obstetrics and con- followed as under other circumstances but that the particular susceptibility of the maternity patient, and sometimes of the newborn child, necessitates even greater than ordinary precautions.

[The answer was sent to Dr. Beckman, who makes the following comment:]

1. They should not be admitted to a regular maternity service.
2. Every maternity hospital should have a detention unit where mother and babe have individual quarters.
3. Regular nursing personnel could attend these patients, observing individual isolation technic.
4. The cost of such care would be prohibitive for practical application.
5. The mother so exposed and in labor should not be left in the infectious environment of her home.
6. The problem thus becomes a public health problem and solution will probably eventually be found by creating such detention quarters either from private philanthropic sources or from state and national sources of revenue.

CHRONIC URETHRITIS IN WOMEN

To the Editor:—Please outline the treatment for chronic streptococcus anterior urethritis in a woman. Please give prognosis.
M.D., Michigan.

ANSWER.—Chronic urethritis in the female is practically always a mixed infection; whether it started off as a specific or as a nonspecific one is of no particular importance, since secondary organisms have charge of the situation eventually, often resulting in periurethral fibrosis. Whether the majority of the organisms are streptococci or any other organism is of no great significance. The management of this type of urethral lesion consists essentially of gradual but progressive urethral dilation followed by an injection into the urethra of some mild antiseptic solution the equivalent of 5 per cent mild protein silver. As an adjunct to this local treatment, often the oral administration of sulfanilamide in conservative doses (i.e., 10 grains [0.65 Gm.] with 10 grains of sodium bicarbonate after each meal) for a period of two weeks may be instrumental in helping to eradicate the primary cause, but this alone will have no important influence on curing the local condition.

SNUFFING PITUITARY POWDER AND NASAL ULCER

To the Editor:—A patient is using posterior pituitary powder in the nose for diabetes insipidus. An ulceration has developed on the mucous membrane extending throughout the septal cartilage. Would you kindly let me know of any similar cases reported?
M.D., Michigan.

ANSWER.—It is not stated how the powder is being introduced into the nose. If a glass tube is being inserted directly into the nostril, it is possible that some trauma has resulted. The better way is either to blow the powder into the nose with the tube not actually in contact with the nose or to place the powder in a small paper and have the patient sniff it. There have been no recorded cases in which the powder itself has caused any trouble to the nose. It should be determined whether or not the medication has anything to do with the ulceration. Certainly a flocculation test for syphilis should be done and any other possible cause excluded. If the physician still believes that the powder itself is responsible for this ulceration he should discontinue it for a while, during which time the patient's diabetes insipidus can be controlled with hypodermic injections of solution of posterior

QUERIES AND MINOR NOTES

879

SALT IN DIET AND SALT SUBSTITUTES

To the Editor:—If a patient eliminates sodium chloride from his daily diet completely, will he get enough salt from his food (I am thinking especially of milk, meat, fish and vegetables) to supply his needs under ordinary conditions? I realize that if he sweats profusely he will lose so much salt that it would have to be replenished. Has the value of potassium chloride as a useful and unobjectionable substitute for sodium chloride been established?

ANSWER.—The amount of sodium chloride contained in a mixed unsalted diet is adequate to supply ordinary needs. By omitting the use of salty foods and avoiding the addition of salt in the preparation of foods, the amount of sodium chloride contained in the diet can with difficulty be made less than 2 Gm., and this amount is sufficient under ordinary conditions. Potassium chloride is an unsatisfactory substitute to use for seasoning because of its metallic taste.

M.D., Louisiana.

GOAT'S BLOOD FOR GASTRIC ULCER

To the Editor:—Is the injection of goat's blood good for gastric ulcers?

Leslie Randall, M.D., Licking, Mo.

ANSWER.—The inquirer enclosed a letter stating that an article on this subject had been published in the *Journal of Dairy Science*. The publishers of this journal were unable to identify the article or give us any information concerning it. The first man to suggest the injection of animal blood for the treatment of various conditions was Bier (*Med. Welt* 8: 1267 [Sept. 8] 1934). His theory was that the parenteral injection of disintegrated substances of the body, or indeed of any foreign organic material, would provide the most powerful stimulus for the defensive and reconstructive activities of the organism. He used two kinds of blood, sheep and beef, but gave no report on gastric ulcer.

The only possible good results that injections of goat's blood could accomplish would seem to be the questionable ones obtained from nonspecific protein therapy. According to Eusterman and Balfour (*The Stomach and Duodenum*, Philadelphia, W. B. Saunders Company, 1936, p. 292), "nonspecific protein therapy undoubtedly affords symptomatic relief in the majority of cases, but in surgically removed ulcers there were no signs of healing in cases in which this form of therapy was employed." Felix Cunha (*Am. J. Surg.* 23:219 [Feb.] 1934) reports favorable results with a combination of lipoproteins and emetine, known as synodal, in four cases of gastric ulcer. Cecil (*THE JOURNAL*, Dec. 7, 1935, p. 1846) states that "one would hardly expect protein therapy to have any value in the treatment of peptic ulcers. In view of the marked tendency of ulcers to periodic remissions and exacerbations, the results must be accepted with considerable reservation." It must not be forgotten that any treatment for peptic ulcer administered enthusiastically is likely to give temporary relief.

IONTOPHORESIS FOR ARTHRITIS

To the Editor:—1. What is the status of iontophoresis with acetyl-beta-methylcholine chloride in the treatment of rheumatoid and other types of arthritis? 2. What voltage and milliamperage of galvanic current are used? 3. What is the percentage of the solution used and how is it made up? 4. Is there any danger of any unpleasant or serious complications arising from this type of treatment?

M. B. Guthrie, M.D., Columbus, Ohio.

ANSWER.—In 1934 the Kovacs recommended the use of acetyl-beta-methylcholine chloride (mecholin: mecholy) by iontophoresis as superior to iontophoresis with histamine in the treatment of rheumatoid (atrophic) arthritis; the effects of the former were more lasting, less unpleasant and more effective. Means of this method a peripheral vasodilatation lasting a number of hours was produced. Of thirty patients suffering from rheumatoid arthritis, 90 per cent were "improved." Patients with osteo-arthritis were less notably relieved. About half a dozen additional reports on the effects of iontophoresis with acetyl-beta-methylcholine chloride for rheumatoid arthritis have appeared. Abel treated eleven patients by this means; ten were "definitely improved." Patients having spondylitis were not relieved. Of Mathae's thirty-two patients, 72 per cent obtained "good results." Boyd, Osborne and Markson treated fifteen patients; thirty-six patients, 57 per cent were "helped"; "some became symptom free." Of Phillips's twenty patients only two were improved and the method was abandoned as useless. Kling and Sashin insist that the method was abandoned with mecholy, and the results thereof, are much inferior to those produced by histamine.

These results certainly are not impressive. Only a few patients were treated in each series. No real control studies were instituted. Apparently some patients obtained variable degrees of temporary relief, presumably from the vasodilating effect of the drug. Cures were not obtained. From 50 to 75 per cent of arthritic patients are "relieved" by application of a wide variety of unrelated measures. When it is remembered that the results of sympathectomy, the ultimate in peripheral vasodilatation, were disappointing in the treatment of rheumatoid arthritis, one should not expect much from methods which provide such transient vasodilatation.

Although no adequate comparison between results obtained by mecholy iontophoresis and ordinary physical therapy has been made, it does not seem to be proved that treatment by iontophoresis with drugs is preferable to the simpler, less elaborate and less expensive methods of physical therapy which can be used in the physician's office and continued daily in the patient's own home.

CONTACT DERMATITIS FROM TETRA-ETHYL GASOLINE

To the Editor:—Following contact with a standard brand of gasoline containing tetra-ethyl lead (one of the so-called premium grades), a filling station operator complained of an erythematous papular rash on the areas of contact (hands). The lesion was itchy and progressed to a diffuse inflammatory type, the papules becoming confluent within several days. Patch tests with this and with another brand of leaded gasoline gave similar reactions; there was no reaction to ordinary gasoline which did not contain tetra-ethyl lead. There are no indications of systemic lead poisoning. Treatment to date has included avoidance of the irritant, intravenous sodium thiosulfate and local application of calamine lotion. There has been no improvement. The patient's past history includes no known allergic conditions. As I am unable to find anything regarding contact dermatitis due to this cause in the literature available to me, any information you can give me regarding its incidence and treatment will be appreciated.

M.D., Minnesota.

ANSWER.—Contact dermatitis attributed to tetra-ethyl lead in ethyl gasoline has not often been reported. However, a case similar to this one is reported by David W. Johnson under the title "Dermatitis Caused by Ethyl Gasoline" in the *Archives of Dermatology and Syphilology* (28:174 [Aug.] 1933). Tetra-ethyl lead ($Pb[C_2H_5]_4$) is sold in the form of ethyl fluid, a mixture of from 60 to 75 per cent of tetra-ethyl lead or ethyl dibromide, all of which substances are poisonous. When applied to the skin, tetra-ethyl lead is readily absorbed and if applied in sufficient quantity will produce lead poisoning. It is corrosive to the skin only after prolonged contact and is added to gasoline only in the proportion of about 1:1,000 to 1:1,400. Hence, in order for tetra-ethyl lead to be the cause of dermatitis due to contact with ethyl gasoline, extreme hypersensitivity to it must be present. The fact that the patient shows no symptoms of lead poisoning indicates that there was but little exposure.

The cases of systemic lead poisoning reported in the literature as caused by tetra-ethyl lead do not mention any cutaneous lesions except itching. Dermatitis due to ordinary gasoline has often been reported, and that gasoline is capable of causing sensitization is shown by J. B. Biederman in his article "A Case of Contact Dermatitis Produced at a Distance by a Sensitizing Agent" (*THE JOURNAL*, June 27, 1936, p. 2236). The unusual part of both Dr. Johnson's report and this one is that patch tests with ordinary gasoline gave no reactions. It is generally experienced that patch tests with undiluted gasoline left on the skin for twenty-four hours always cause a blister, even on normal persons. As a result of this it is recommended that, in order to test for sensitivity to gasoline, patch tests be done with equal parts of gasoline and olive oil.

If the patient is sensitive only to ethyl gasoline, removal of contact with it for several months should clear up the eruption.

However, the patient may be polysensitive, and it is suggested that patch tests with other substances with which he comes in contact be performed.

The use of soothing applications, such as calamine lotion, is proper local treatment for contact dermatitis. Since it is stated that the patient shows no indications of systemic lead poisoning, the use of intravenous sodium thiosulfate would be purely empirical.

QUININE AND ATABRINE IN MALARIA

To the Editor:—What is the present opinion regarding the simultaneous treatment of malaria with quinine and atabrine? Can they be used together safely in full doses? If not, is it good practice to use them together at all and in what suggested dosages? Is there more danger in using them together in cerebral cases?

M.D., Siam.

ANSWER.—Quinine and atabrine can be safely used simultaneously. There is neither pharmacologic nor clinical evidence of any antagonism between these two malaricidal drugs. For oral administration the full therapeutic dose of each may be prescribed for the first five days of treatment, i. e. 10 grains (0.65 Gm.) of quinine and $1\frac{1}{2}$ grains (0.1 Gm.) of atabrine each, three times a day. This is followed by the administration of 10 grains of quinine daily for from three to five weeks or atabrine in $1\frac{1}{2}$ grain amounts three times a day for four or five days. Some physicians believe that this combined therapy is more efficacious than quinine or atabrine alone. However, in some cases the combined treatment fails to eradicate the plasmodia. In comatose patients and in infections in which the circulating blood is loaded with trophozoites and schizonts, intramuscular injection of the two drugs can be safely employed simultaneously. For the first two or three days 8 grains (0.5 Gm.) of quinine dihydrochloride in 4 cc. of distilled water or physiologic solution of sodium chloride and $3\frac{1}{2}$ grains (0.2 Gm.) of atabrine dihydrochloride or atabrine musonate in 10 cc. of distilled water are administered two or three times a day. Beginning with the fourth day, atabrine is given by mouth in the usual amounts for four or five days. In cases of delirium, collapse or coma, either quinine dihydrochloride or atabrine dihydrochloride can be utilized intravenously to reduce the critical symptoms, but the wisdom of giving the two drugs by vein during the same crisis is seriously questioned.

CELIAC DISEASE

To the Editor:—I should like to take exception to several of the statements given in *The Journal* May 27 in response to a query on celiac disease. It was stated that the fats are at fault. This idea is held by many eminent pediatricians but is unfortunately incorrect. Although there is a low tolerance for fats, this is due to the fact that there is no available carbohydrate for their metabolism. The large fatty stools that are present in celiac disease are misleading. It has been shown in the human subject that under certain conditions even on a fat free diet there can be an excess of fatty acids in the stool. Treatment is wholly dietary; milk as such or as buttermilk or lactic acid milk must be excluded. In its place protein milk should be used either powdered or prepared in fluid state, or milk and water, equal parts, plus calcium caseinate brought to a boil. Carbohydrates in the form of sugar, pastry, bread, cereals, candy and syrups must be rigidly excluded. Carbohydrates may be used in the form of ripe bananas in unlimited quantities, and later in the treatment other fruits and vegetables, with the exception of potato, may be carefully tried. Unsweetened fruit juices are usually well borne. Meat, egg white and cottage cheese may be used in any desired quantity. Vitamin D is the only vitamin that is low in the celiac diet and should be used only in a highly concentrated form. Experience has shown that a strict diet carried out for less than one year may result in relapse later. After twelve months of the diet an attempt may be made to introduce a cereal or bread; if no ill effects follow within three months whole milk may be introduced, and if at the end of the second three months all is well the patient is cured and no relapse will occur from any cause. If, however, there should have been a recurrence of symptoms within the three months period, the offending material in the diet should be withdrawn at once and another three months period allowed to elapse before being tried again. It will be found that sooner or later the forbidden foods can be tolerated. Iron in some form should be used. There is no objection to calcium; but the celiac diet is rich in calcium. Liver extract parenterally as Rhoads uses it in sprue is decidedly helpful. Prognosis is excellent, recovery is complete, future health, strength and stature are normal. A normal diet can be taken without gastrointestinal disturbance.

Medical Examinations and Licensure

COMING EXAMINATIONS

STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in *The Journal*, August 19, page 707.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: Parts I and II. Medical centers having five or more candidates desiring to take the examination, Sept. 11-13. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th Street, Philadelphia.

SPECIAL BOARDS

AMERICAN BOARD OF ANESTHESIOLOGY: An Affiliate of the American Board of Surgery. Oral. Part II. Philadelphia, Oct. 14-15. Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York.

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: Written. Various large cities in the country, Oct. 9. Applications must be received by the Secretary by Sept. 1. Oral. Philadelphia, Nov. 3-4. Sec., Dr. C. Guy Lane, 416 Marlboro St., Boston.

AMERICAN BOARD OF INTERNAL MEDICINE: Written. Various sections of the United States, Feb. 19. Formal application must be received on or before Jan. 1. Sec., Dr. William S. Middleton, 1301 University Ave., Madison, Wis.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: Written examination and review of case histories (Part I) for Group B candidates will be held in various cities of the United States and Canada, Jan. 6. Applications for admission to Group B, Part I, examinations must be on file not later than Oct. 4. General oral and pathological examinations (Part II) for all candidates (Groups A and B) will be conducted in Atlantic City, N. J., June 8-11. Applications for admission to Group A, Part II examinations must be on file not later than March 15. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6).

AMERICAN BOARD OF OPHTHALMOLOGY: Written. Various cities of the United States and Canada, March 9. Oral. New York, June 10. Formal applications must be received before Jan. 1. Sec., Dr. John Green, 6830 Waterman Ave., St. Louis.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Boston, January. Applications must be filed on or before Nov. 1. Sec., Dr. Fremont A. Chandler, 6 N. Michigan Ave., Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY: Chicago, Oct. 6-7. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

AMERICAN BOARD OF PATHOLOGY: Memphis, Nov. 22-23. Sec., Dr. F. W. Hartman, Henry Ford Hospital, Detroit.

AMERICAN BOARD OF PEDIATRICS: New York, April 30 and May 1. Kansas City, Mo., preceding the Region III meeting of the American Academy of Pediatrics. Seattle, preceding the Region IV meeting of the American Academy of Pediatrics. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Ill.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: New York, December. Sec., Dr. Walter Freeman, 1028 Connecticut Ave. N.W., Washington, D. C.

AMERICAN BOARD OF RADIOLOGY: Atlanta, Ga., Dec. 9-11. Sec., Dr. Byrl R. Kirklind, 102-110 Second Avenue S.W., Rochester, Minnesota.

AMERICAN BOARD OF UROLOGY: Chicago, Feb. 9-11. (The only examination session to be held in 1940.) Case reports must be submitted not later than November 9. Sec., Dr. Gilbert J. Thomas, 1009 Nicollet Ave., Minneapolis.

Kentucky June Examination

Dr. A. T. McCormack, secretary, State Board of Health of Kentucky, reports the written examination held at Louisville, June 7-9, 1939. The examination covered eleven subjects and included 110 questions. An average of 70 per cent was required to pass. Eighty-three candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
School of Medicine of the Division of the Biological Sciences	(1937)		83
University of Louisville School of Medicine	(1938)		90
(1939) 77, 77, 78, 78, 79, 79, 79, 79, 79, 79, 79, 79, 80, 80, 80, 80, 80, 80, 80, 80, 81, 81, 81, 81, 81, 81, 81, 81, 82, 82, 82, 82, 82, 82, 82, 82, 82, 82, 83, 83, 83, 83, 83, 83, 83, 83, 84, 84, 84, 84, 84, 84, 84, 84, 85, 85, 85, 85, 85, 85, 86, 86, 86, 86, 88, 88, 88, 88			
Harvard Medical School	(1937)		80
Duke University School of Medicine	(1939)	79, 79	
University of Tennessee	(1939)		83
Vanderbilt University School of Medicine	(1938)		81
Medical College of Virginia	(1938)		

Ten physicians were licensed by reciprocity and two physicians were licensed by endorsement from May 18 through July 22. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
George Washington University School of Medicine	(1936)		Louisiana
University of Illinois College of Medicine	(1936)		Illinois
Tulane University of Louisiana School of Medicine	(1935)		Mississippi
University of Cincinnati College of Medicine	(1937)		Ohio
Western Reserve University School of Medicine	(1935)		Ohio
University of Tennessee College of Medicine	(1935)		Tennessee
Vanderbilt University School of Medicine	(1936, 2)		Tennessee
Marquette University School of Medicine	(1933)		Wisconsin
School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
University of Rochester School of Medicine	(1933)		N. B. M. Ex.

Book Notices

The Principles and Practice of Ophthalmic Surgery. By Edmund B. Spaeth, M.D., Associate Professor of Ophthalmology in the Graduate School of Medicine of the University of Pennsylvania, Philadelphia. Cloth. Price, \$10. Pp. 835, with 1,035 illustrations. Philadelphia: Lea & Febiger, 1939.

In the review of as comprehensive a textbook as this, it seems more important to tell the reader what is in the book rather than write a polemic on the differences of opinion of the author and the reviewer. Here is a new textbook, covering the standard principles and practices of ophthalmic surgery with but few omissions. Adopting a somewhat different form from the usual, the author properly devotes more time and space to adequate discussion of indications for operation and to thorough descriptions of after-care and complications than to mere technical statements of operative procedures. It is an elaboration of the method used so successfully by Elschnig in the "Operationslehre" of the Graefe-Saemisch Handbuch. Each aspect has an adequate bibliography, starting wisely about where the Elschnig book left off, thus not confusing the reader with extensive references to the older and now abandoned methods. There are twenty-six chapters in the book, covering anesthesia and surgical technic, surgery of the eyeball and ocular adnexa, reconstructive and corrective plastic surgery of the eyelids, and the surgery of special conditions, such as glaucoma and retinal detachment. A careful cross index of authors as well as of general material simplifies the use of the text. Naturally different values would be assigned to various chapters, according to the different views of readers. But all will undoubtedly agree that the parts devoted to plastic surgery are particularly good, although the standard is kept uniformly high throughout. Nearly all the illustrations are black and white. Especially excellent and understandable are the diagrams. Unfortunately, the close-ups of the actual eye do not mean much and will undoubtedly be replaced in the next edition, which the demand will surely require. The full face or head views are much better. By and large, we have a new textbook on surgery of the eye, well written and of unquestionable value to all ophthalmologists performing operative work in that special field. The reader is given the opportunity of digesting opinions of various surgeons on various procedures, including those of the author based on his own extensive experience. Thus to the man of limited experience the book is of exceptional value.

Éléments d'embryologie. Par A. Celestino da Costa, professeur d'histologie et d'embryologie à la Faculté de médecine de Lisbonne. Paper. Price, 120 francs. Pp. 494, with 386 illustrations. Paris: Masson & Cie, 1938.

This is a textbook on embryology in all its biologic aspects. It is modeled on the *Traité de Brachet*, adapted for the use of medical students by the omission of detail and, in the section on organogenesis, by emphasis on the conditions in man. The preface says "The object is to present to students the elements of embryology which they need not only for a better understanding of normal and abnormal anatomy and physiology but also for their general culture" and "pour la formation de leur esprit biologique." These ends are admirably achieved. It has the clear logical arrangement so characteristic of the French, and the style is often sparkling and picturesque. On page 255 one reads that "l'oeuf devient sensible à la présence d'un génome d'une autre espèce." In the first section the gametes are considered and the embryologic aspects of heredity—a feature too often neglected in medical courses. The second section presents the general aspects of vertebrate embryology and leads up to the recent experimental analyses of the factors concerned in the orderly sequence of events in development. The old ideas of three germ layers with totally different and fully determined potencies is thoroughly disposed of. In the section on organogeny there is no effort to make the student familiar with the anatomy of a series of embryos; models and reconstructions are used sparingly. Most of the illustrations are taken from the author's own mammalian series. Histogenesis, which rarely means much to the student, is not considered in any detail. On the other hand, every opportunity is taken to stress fundamental

features, as in the chapters on cranial nerves and the urogenital system. The author's knowledge of the literature is cosmopolitan and in most respects abreast of the time. One can object to the inclusion of old data in the table of ossification centers, since our ideas of the age of embryos have been considerably modified since the days of Wilhelm His. In general this table gives an appearance of exactness which is necessarily fictitious. The use of old reconstructions of the embryonic vascular system is unfortunate. Enough is known now of the anatomy of young human embryos for one to say confidently that Eternod's reconstruction of the vessels in his embryo "Vieul" was a rather forced interpretation of the irregular capillary net present at that stage.

Wide Road Ahead: The Story of a Woman Bacteriologist. By Anne B. Fisher. Cloth. Price, \$2.50. Pp. 276. New York: E. P. Dutton & Co., Inc., 1939.

This book is a slight thing which is either autobiographical, as suggested in the dust cover blurb, which says that the author "herself has lived through all the experiences she describes," or fictitious, as indicated in a note facing chapter 1, which says "All characters in this book are fictitious. Any resemblance to a living person is a coincidence." It is a story of a young woman bacteriologist who overcomes in Horatio Alger best success story fashion the handicaps of her youth, her sex, the skepticism of ranchers who cannot visualize a female "bug doctor," the limitations of official red tape and numerous other obstacles. She starts out with a passionate devotion to bacteriology and performs many wonderful feats, including the teaching of doctors to abandon their old fashioned methods and use pneumonia typing and serum therapy. In the process of overcoming baseless prejudice against her youth and sex she humiliates an older bacteriologist, outwits the community skinflint, becomes involved in a tong war and escapes being murdered by a man whose sweetheart's stomach she analyzes after the lady is found dead at the scene of an alcoholic brawl. Not so good!

Über die Resultate der Diabetesbehandlung in Finnland. Von Eero Ponteva. Acta medica Scandinavica, Supplementum 88. Paper. Pp. 108. Stockholm, 1938.

An excellent review of diabetic therapy, particularly since the introduction of insulin occupies the first chapter, but the monograph is of chief interest because of the careful statistical studies concerning the patients themselves. Eighty-six patients formed a group before and 645 after insulin was begun and the latter comprised patients treated between October 1923 and July 1936 in the second medical clinic of the University of Helsinki. Whereas 19 per cent of the eighty-six patients treated before the employment of insulin died in the clinic, the mortality among 645 patients later treated in the clinic was only 6.8 per cent. Coma fell from 81 per cent in the former to 27 per cent in the latter. In fact, of the thirteen patients in actual coma and in precoma before the use of insulin all died and only 24 per cent of those after it was begun. Before insulin the ratio of the number of diabetic patients to the total number of patients in the clinic was 2.1 per cent but later rose to 7.9 per cent and yet the duration of stay fell from 6.7 to 3.9 weeks. On the date of the completion of the survey, Sept. 1, 1936, of all the cases since discharge from the hospital, 51 per cent of the insulin treated patients were living, 46.4 per cent dead, and 2.6 per cent untraced. The cause of death of the fatal cases in 45.1 per cent was diabetes; pulmonary tuberculosis claimed 18.8 per cent, and circulatory disease 15.3 per cent. The average age in the fatal cases at death was 44.4 years and the duration of the diabetes on the average four years. Mortality in general varied little with the age of the patients, but the duration of the disease rose with the age. Thus, among young people the duration of the disease was three years, among patients in middle age three years and ten months, and with old people five years and one month. Mortality varied with the localities from which the patients came. Thus, in Helsinki it was 28 per cent, in the provincial cities 32.7 per cent, and in the country districts 48.5 per cent. Mortality likewise depended on financial circumstances and on the degree of education of the patient. It was 43.1 per cent for

workmen, 58.8 per cent for peasants and only 33.9 per cent for the educated class. Workmen succumbed to diabetes in 22.9 per cent, peasants 31.9 per cent and only 5.3 per cent of the educated. The duration of life of the patients similarly varied but really was surprisingly small. Thus, among workmen it was three years and five months, peasants three years and ten months, and the educated class five years and four months. Disregard of diet occurred frequently, and 45 per cent totally gave it up and the cause in 46.8 per cent of all cases was lack of funds and in 34.3 per cent the impossibility of securing enough vegetables. Only 9.6 per cent of the workmen reported obtaining sufficient vegetables. On the other hand, only eight of the 184 patients taking insulin lacked it, and four of these because of doctors' advice. Assistance in securing insulin was given to 33.9 per cent of the patients. Excellent health characterized 30.8 per cent of the 266 patients who answered the question and 63.2 per cent were able to carry on their work, whereas 28.9 per cent sought lighter labor and 7.9 per cent were completely disabled, although in only 3.8 per cent was this due primarily to the diabetes itself. Among the educated class 76 per cent were able to carry on completely, but among the workmen and peasants the figure was 57 per cent. Whether or not the patient followed diet had little to do with his ability to work. Even of the patients recovering from coma, 60 per cent were able to follow their occupations.

Alice in Virusland. By Paul F. Clark, Professor of Bacteriology, University of Wisconsin Medical School, Madison. [Reprinted from the *Journal of Bacteriology*, September 1938.] Boards. Price, \$1. Pp. 23, with 5 illustrations. Madison: I. L. Baldwin, Agric. Hall, Univ. of Wis., 1938.

Professor Clark takes a germ's eye view of the human race and utilizes the occasion of his presidential address to the Society of American Bacteriologists to express an opinion which is far from favorable. Paraphrasing Alice in Wonderland, he takes Alice by virtue of a shrinking potion into Virusland, where she gets an unvarnished opinion of the human race from the microscopic creatures. This is effectively summed up by a verse from a poem "The Coccus and the Spirochaete":

"Should we permit," the Coccus asked,
"These silly beasts to thrive,
Who call themselves the lords of earth
Yet selfishly connive
Freedom, dignity and peace
From many lands to drive?"

It is an extraordinarily clever and stimulating, though pessimistic, production. The epilogue, which the author refrained from reading at the annual banquet because it was "thought to be in harmony with the philosophy of the paper but not with the spirit of the Annual Banquet," is a quotation from Epictetus: "He who remembers what man is can be discontented at nothing which happens."

Schafer's Essentials of Histology Descriptive and Practical for the Use of Students. Edited by H. M. Carleton, M.A., B.Sc., D.Phil. Fourteenth edition. Cloth. Price, \$5. Pp. 618, with 665 illustrations. Philadelphia: Lea & Febiger, 1938.

The popularity of this English book is attested by its many editions since it first appeared, fifty-three years ago, under the authorship of the late Professor Sharpey-Schafer. In this country it would seem inevitable that the book would have to contend with serious competition by better American textbooks of histology. As compared with earlier editions, the general character of the book is the same except that some older illustrations have been replaced. The text is profusely illustrated but the uneven quality of the illustrations produces a somewhat disturbing impression. A great many original and rather old illustrations by Sharpey-Schafer and other early anatomists (Henle, Waldeyer, Retzius, Hering, Kölliker, Ranvier, Schwalbe, Schultze) alternate with reproductions of photomicrographs. The quality of the latter is often unsatisfactory, and it may be doubted whether they are of value in presenting good structural details. Today we are used to expect excellent illustrations in any textbook dealing with morphologic sciences. Many of the illustrations pertain to animal rather than to human tissues. The text of the fifty chapters is exceedingly brief and often incomplete. This may be justified by the scope and title of the book. One might ask, however, why only the least

defensible theory on the origin of the lymphatic system is mentioned, why the corpus haemorrhagicum is not described as such or why the origin of the parathyroids and of the thymus is reported to be from the "third and fourth branchial clefts" rather than from the corresponding pharyngeal pouches. The book is written for the use of students. It would appear to be suitable for a general course in colleges rather than for medical students. There is an appendix on histologic methods and a good index.

Common Happenings in Childhood. By Sir G. Frederic Still, K.C.V.O., M.A., M.D., Physician Extraordinary to H. M. The King. Cloth. Price, \$1.75. Pp. 180. New York & London: Oxford University Press, 1938.

A pediatrician of standing, widely recognized as the best type of family practitioner, contributes here his views on crying, laughing, temper, tiredness, appetite, fears and antipathies, sleep and school. He tells his story with numerous references to actual cases, to history, to literature and to life. His is the wisdom of years of practice, and as a result this is one of the most sensible books available on the subjects that it concerns.

La médecine d'urgence: Symptômes, diagnostic, traitement immédiat, formulaire. Par le Dr. J. Oddo. Introduction du Professeur Grasset. Ouvrage couronné par l'Académie de médecine (Prix Harter 1915). Seventh edition. Paper. Price, 120 francs. Pp. 839. Paris: G. Doin & Cie, 1939.

This book deals with medical emergencies. The author, obviously a master of descriptive art as well as a physician of wide clinical experience, has succeeded in producing a medical classic. Urgent medical problems are portrayed vividly, enabling the reader to visualize a patient in the actual grip of the emergency under discussion. A more concise description of relatively minor manifestations, the mechanisms underlying these features and possible variations then follows. Differential diagnosis is discussed from the point of view of the physician confronted by the emergency, thus furthering the decidedly clinical implication of the book. The subject matter begins with emergencies of the respiratory tract and includes croup, asthma, pulmonary embolus or hemorrhage, hemoptysis, acute pulmonary edema, pneumothorax, copious expectoration from rupture of a suppurating area into a bronchus, and thoracic pain. The vivid clinical description of each condition is followed by a detailed discussion of the immediate treatment, but prevention, management of complications and surgical intervention, when necessary, are not neglected. A similar pattern is followed for diseases of the circulatory, digestive, renal and nervous systems, and a chapter is devoted to gout, cerebral rheumatism, diabetic coma and pernicious malaria. The book closes with a brief chapter on the accidents produced by the arsphenamines and one on poisons. The reader will be fascinated by the author's description of disease pictures and will gain an excellent impression of the French point of view. Some of the ideas, however, either have been discarded in this country or have never gained a secure foothold here. This pertains particularly to therapy, notable examples being the rather frequent employment of bleeding, cupping and the use of counterirritants. A more significant fault is the failure to lay adequate emphasis on the value of mercurial diuretics in the treatment of severe edema. These and other differences of opinion do not minimize the value of this section of the book, as there are many suggestions which the physician will do well to remember.

Positioning in Radiography. By K. C. Claiborne, in charge, Hford Limited Radiographic Technical and London. Cloth. Price, \$28. Pp. 482, with 1,100 illustrations. C. V. Mosby Company, 1939.

This is the most elaborate book on roentgenographic technique ever published. The paper is excellent. The presswork is impeccable. The illustrations are balanced between photographs and drawings of an instructive character and an adequate number of roentgenograms showing the results which appear in the roentgenographic film. An extraordinary amount of preparatory work was undertaken to produce this master guide to roentgenographic technique. The price is not excessive, considering the magnificence of the illustrations, the carefully worded descriptive text and the accurately detailed instruction as to the exposure factors. It is hardly possible to speak in terms of too much praise for this beautiful volume.

BOOK NOTICES

883

The Circulation of the Brain and Spinal Cord: A Symposium on Blood Supply. The Proceedings of the Association, New York, December 27th and 28th, 1937. Editorial Board: Stanley Cobb, M.D., Chairman, Angus M. Frantz, M.D., Wilder Penfield, M.D., and Henry A. Riley, M.D. Association for Research in Nervous and Mental Disease, Vol. XVIII of a Series of Research Publications. Cloth. Price, \$10. Pp. 790, with 282 illustrations. Baltimore: Williams & Wilkins Company, 1938.

This volume includes the papers presented at the meeting of the Association for Research in Nervous and Mental Disease which met in New York, Dec. 27 and 28, 1937. There are twenty-six separate papers, or chapters, and a critical discussion of the entire symposium by Dr. Stanley Cobb. The subject matter has been divided into three sections: (1) anatomy and physiology, (2) pathology and (3) clinical contributions. Although much of the material is not new and most of it has been presented in separate publications elsewhere, this volume will prove of particular value for ready reference and to persons who do not have good library facilities available. Chapter iv, "The Capillary Bed of the Paraventricular and Supra-Optic Nuclei of the Hypothalamus," by K. H. Finley, is well prepared and most interesting. Finley has shown that these nuclei have a capillary bed which, except for a nucleus in the brain stem, is more dense than any other region of the central nervous system. This is undoubtedly of considerable functional significance. Chapter v on "The Cerebral Vessels studied by Angiography," by A. R. Elvidge, is undoubtedly the best presentation of the subject of cerebral arteriography available in English. Chapter vii, "The Innervation of the Intercranial Blood Vessels and Dural Sinuses," by F. L. McNaughton, is a full and useful presentation. Chapter x, "The Action of Chemical Substances on Cerebral Blood Vessels," by C. F. Schmidt and J. P. Hendrix, is worthy of careful study by all who are interested in the subject of cerebral circulation. Chapter xii, "The Influence of Circulation on the Activity of Nerve Cells," by D. W. Bronk, and chapter xiii, "Brain Metabolism and Circulation," by R. W. Gerard, indicate the importance of the circulation for the maintenance and alteration of nervous activity. Chapter xiv, "Focal Alterations in Subcortical Circulation Resulting from Stimulation of the Cerebral Cortex," by von Santha and Cipriani, describes a series of experiments which demonstrate that localized electrical stimulation of the cerebral cortex is associated with sharply localized vasodilatation in the related subcortical centers. The caudate nucleus, the thalamus and the geniculate bodies were studied. These experiments confirmed the localized projection of the various nuclei of the thalamus as established by the physiologic studies of Dusser de Barenne and the anatomic studies of Le Gros Clark and of Walker. In chapter xxi, Soma Weiss presents a thorough review of the physiology of the carotid sinus mechanism and its clinical significance. Chapter xxii, "The Circulation of the Epileptic Brain," by Wilder Penfield, presents this author's extensive experience with the vascularity of such brains as observed at operation. The observations of Graham and Wolff in chapter xxiii on the mechanism of migraine headache are important in the study and understanding of this obscure condition. The concluding discussion by Dr. Cobb will prove of value not only in summarizing and crystallizing the material presented but in a critical evaluation of it as well. This chapter adds greatly to the value of the book. A footnote by Dr. Cobb, to be found on page 728, is worthy of preservation and fuller circulation: "Physics, anatomy, physiology and neurology are merely convenient administrative terms used to designate certain departments in a university. To believe that such terms have any biological significance is to surrender to the academicians! Biological data should not be classified departmentally; the facts apply to living organisms and may have significance for many departments of science."

Preclinical Medicine: Preclinical States and Prevention of Disease. By Malford W. Thewlis, M.D., Attending Specialist, General Medicine, United States Public Health Hospitals, New York City. Cloth. Price, \$3. Pp. 223, with 12 illustrations. Baltimore: William Wood & Company, 1939.

In the preface, Dr. Thewlis grants that there is no clearcut demarcation between clinical and preclinical medicine and, of course, that is evident throughout the book. A rather disappointing feature is the inclusion everywhere of so much material regarding disease prevention. Of course there is no subject more important than disease prevention, but this is supposed to be a book on preclinical medicine. The author evidently wants to get a vast amount of information before his readers. One result of this is a short, jerky style which may be for-

given, but it leads to such short, snappy sentences as "The next worldwide epidemic of influenza is expected in 1948." There is no word of explanation or any connection with anything except the general subject of influenza. Every pioneer makes the way easier for the next comers. Dr. Thewlis is actually pioneering in preclinical medicine. There are certainly preclinical states in medicine and they are certainly of great importance. The next books will be better because Dr. Thewlis has had the courage to make the beginning.

Children with Delayed or Defective Speech: Motor-Kinesthetic Factors in Their Training. By Sara M. Stinchfield, University of Southern California, and Edna Hill Young, Principal, Hill-Young School of Speech, Los Angeles, California. Cloth. Price, \$3. Pp. 174, with illustrations. Stanford University Press; Stanford University Press; London: Oxford University Press, 1938.

Here is a technical work on delayed speech development and the practical therapy for overcoming it used in the Hill-Young School of Speech. In the therapy, interest is centered on speech movements and word patterns. The appendix provides numerous illustrations showing what is meant by this technic.

So You're Going to Stop Smoking! By J. C. Furnas. Second edition. Cloth. Price, \$1.25. Pp. 97. New York: Simon and Schuster, 1939.

The author, who is neither a physician nor a psychologist, collected information about smoking by sending letters to a number of celebrities asking them about the smoke habit. He has collected also a good deal of data both from physicians and from medical literature on smoking and what it does to you and for you. In an appendix are some choice sentences chosen from some of the questionnaires and an abstract of replies. Some of these data are interesting. It is interesting to know that John Charles Thomas chewed tobacco, that Henry L. Mencken has 100 pipes, that Rupert Hughes smokes incessantly while awake and that most celebrities haven't the slightest idea what they like about smoking but a lot of them know what they dislike.

On and Off the Campus. By Guy Stanton Ford. With a biographical introduction by George E. Vincent. Cloth. Price, \$4. Pp. 511, with portrait. Minneapolis: The University of Minnesota Press; London: Oxford University Press, 1938.

This volume was published to honor Dean Ford's twenty-fifth anniversary as head of the graduate school of the University of Minnesota. There is an introductory biographic sketch in appreciation by Dr. George E. Vincent. The collected writings included are divided into essays having to do with Dr. Ford's contributions as a publicist, historian, educational administrator and editor. The editorials are reprinted from Sunday editions of the *Minneapolis Journal*, except the one which appeared in the *St. Paul Pioneer Press*. They are written in substantial, direct English and they are inspiring. Some of them are witty and the wit penetrates.

Sir Kenelm Digby: Writer, Bibliophile and Protagonist of William Harvey. By John F. Fulton, M.D. Cloth. Pp. 75, with 7 illustrations. New York: Peter & Katharine Oliver, 1937.

This paper was read before the Grolier Club in April 1937. It is artistically printed and handsomely illustrated and concerns a great literary figure who was also a physiologist and a philosopher. He was among the first to appreciate the importance of the discovery by William Harvey of the circulation of the blood and he was a strong advocate of that doctrine. The volume is printed in a special edition of only 300 copies and should be a prize to have in the library.

The Wisdom of the Body. By Walter B. Cannon, M.D., Sc.D., LL.D., George Higginson Professor of Physiology, Harvard Medical School, Boston. Second edition. Cloth. Price, \$3.50. Pp. 333, with 40 illustrations. New York: W. W. Norton & Company, Inc., 1939.

The first edition of this book was published in 1932. The present is a revised and enlarged edition, in which a report of additional researches, particularly all the work on homeostasis, is included. The volume is written with the quality, the accuracy and the thoroughness that have always characterized Dr. Cannon's contributions.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts: Pneumonia Attributed to Trauma; Selection of Physician by Employee.—The plaintiff, during the course of his employment, received a blow on his chest. Pneumonia and empyema ensued. Contending that his disability was due to the blow on his chest, the plaintiff brought proceedings under the workmen's compensation act of Michigan. The commission awarded compensation and the defendant company appealed to the Supreme Court of Michigan.

In the proceedings before the deputy commissioner, the plaintiff testified that after the accident his side bothered him a good deal and at noon on the day following the accident he went to the defendant's first aid man, who examined him with a stethoscope and put adhesive tape around his chest. The following day, Friday, the factory was closed and the plaintiff remained at home. On Saturday the plaintiff summoned a physician who pronounced the plaintiff's ailment as pneumonia and removed him to a hospital, where he remained for four months and five days. On Tuesday following the plaintiff's hospitalization, the defendant's foreman received a report from one of his men that the plaintiff was in the hospital. Although the attending physician testified that he had never seen another case of traumatic pneumonia, he attributed the plaintiff's illness to the injury and, on cross-examination, he quoted from various medical textbooks in support of this diagnosis. A physician who assisted in the treatment of the plaintiff confirmed the diagnosis, although he too had never previously attended a case of traumatic pneumonia. The defendant's medical expert witnesses claimed that the pneumonia did not result from any injury as there were no visible evidences of contusions or abrasions on the plaintiff's chest. After reviewing the testimony of these witnesses, the Supreme Court concluded that there was evidence to support the commission's finding of a causal connection between the injury and the subsequent pneumonia and that the presence of such evidence precluded the court from disturbing the finding.

The appeal raised the question as to the defendant's liability for any medical and hospital expenses in connection with the case. The workmen's compensation act of Michigan provides that during the first ninety days after an injury the employer shall furnish, or cause to be furnished, reasonable medical, surgical and hospital services and medicines when they are needed. The defendant claimed that no request was made that it furnish medical care and hospitalization, that it had insufficient notice of the plaintiff's need for such care and that therefore no liability arose under the act. The defendant, the court said, had prompt notice of the fact that the plaintiff claimed that an accident had occurred and, several days later, the company was informed that the plaintiff was in the hospital. The commission found that, on the Saturday prior to the plaintiff's hospitalization on Sunday, his condition was very serious and that immediate medical care was required. The commission concluded that an "emergency" existed, which dispensed with any requirement of notice to the employer, relying on *Gage v. Board of Control of State Hospital*, 206 Mich. 25, 172 N. W. 536, 7 A. L. R. 533. The Supreme Court, however, pointed out that the "emergency" rule of the *Gage* case required more than that the plaintiff's situation be an urgent one. To excuse notice, it must appear that the circumstances are such that there will be an additional delay, dangerous to the life or health of the employee, if efforts are made to contact the employer and afford him an opportunity to furnish the needed medical care.

In the present case, the plaintiff was not admitted to the hospital until some time following his attending physician's diagnosis of pneumonia. There was no showing by the plaintiff that his employer could not have been informed of his needs without causing any dangerous additional delay or that any such

delay would have been involved in giving the employer the opportunity of selecting a hospital and removing the plaintiff to it. The defendant company had no knowledge of the plaintiff's hospitalization until three days after his admittance and, the court said, it cannot be held liable for expenses incurred prior to notification thereof, except that the plaintiff was entitled to the reasonable cost of a consultation with his private physician. The notice that the defendant did receive was sufficient, even though no request was made for medical services, to hold the defendant liable for the expenses incurred by him subsequent to such notification, there being no showing by the defendant that a change in hospital facilities and physicians could not have been made had defendant offered such services. The employee who requires medical attention is presumably not in the best condition to protect his interests and he should not be required to take the initiative and request the employer to supply his medical needs. It is a sufficient burden on the employee, and sufficient protection to the employer, to require that the latter receive notice of the accident and of the fact that the employee is receiving medical attention, in order to charge the employer with medical expenses under the workmen's compensation act.

The case was therefore remanded, with direction to amend the order of award to exclude the items for medical and hospital expense incurred prior to the notification received by the employer.—*McLean v. Eaton Mfg. Co. (Mich.)*, 282 N. W. 150.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1929 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

X-Ray Signs of Pulmonary Embolism with Infarction.

The clinical, pathologic and x-ray features of pulmonary infarction are described by Jellen. The material presented is based on a review of eighteen cases. X-ray evidence of a pulmonary embolus is usually absent unless infarction of the lung takes place. The shadow of an infarct may be absent early and not appear for several days after the onset of a pulmonary embolus. Accentuation of the hilar shadows and pulmonary vessels occurs on the affected side. The region of the costophrenic sulcus is clouded. Triangular, round, oval or irregular shadows are seen in the lung. The diaphragm on the affected side is elevated. Resolution of the infarct at the periphery of the lesion takes place in some cases. There is evidence of associated pleurisy. Localized rarefaction indicating necrosis or abscess formation and pleural thickening and localized fibrosis are present as evidence of old infarcts. Infarcts are distinguished with difficulty in chronic passive congestion of the lungs. An associated pleural effusion, when present, may mask the shadow of the infarct. A prominence of the pulmonary conus, with evidence of right ventricular enlargement, may be observed in "cor pulmonale" if right-sided heart failure is present.

X-Ray Diagnosis and Treatment of Bladder Tumors.—

From June 8, 1928, to June 1935 Pfahler treated fourteen cases of primary inoperable carcinoma of the bladder by roentgen radiation. Seven of these patients, he states, have been free from any demonstrable carcinoma for from two to nine years. Since that date he has treated eight other patients. He points out that his results compare favorably with those of Ferguson and his associates, who have reported forty-eight cases treated by distant external irradiation, twenty of which (thirty-six were examined) showed complete disappearance of the tumors approximately three and a half years later. In the author's

successful cases the smallest estimated tumor dose was 2,450 roentgens. The disease was far advanced and only palliation was expected. The largest tumor dose in his failures was 9,700 roentgens. This patient was apparently well during six months. The bleeding usually stops in from three to four weeks. The bladder generally becomes more irritable under treatment and frequency of urination is increased. Pain in the successful cases is usually relieved in from one to three weeks. The tumor may show a marked reduction within six weeks and total disappearance within three months. The more resistant types may show no reduction in three months and yet may disappear completely within six months. In the unsuccessful cases, partial or complete freedom of all symptoms lasting for several months may be obtained and then hematuria, frequency and pain may recur and failure may result. All in all, some improvement in nearly all inoperable cases may be expected and probably a permanent recovery in 35 per cent. Enough radiation must be delivered into the tumor tissue to destroy the cancer cells. This will require from 3,000 to 4,000 roentgens delivered into the tumor area. This result must be accomplished without serious or permanent damage to the patient's normal tissues. The author plans to give treatment to the patient through as many ports of entry (from four to seven) as is possible which will permit accurate cross-firing on the disease; and, by delivering from 200 to 250 roentgens daily or 150 roentgens twice daily, less damage is done to the overlying tissues and probably the best results are obtained. The author uses 200 kilovolts constant potential and 2 mm. of copper filtration or its equivalent in the Thoraeus filter, usually at a distance of 50 cm., making use either of 2 or 4 milliamperes of current, so as to prolong the irradiation effect as much as possible. The treatment must be given in a manner consistent with the patient's general condition. Radiation sickness does not often occur in these cases. Sufficient tonics and medication are given to keep the patient in as healthy and comfortable a condition as is possible. Repeated examinations by cystoscopy or pneumocystography must be made to determine what has been accomplished and then the treatment supplemented when necessary so as to eliminate all the disease. Some adjuvant treatment may be found which will permit a reduction in the total amount of radiation. When a carcinoma of the bladder reaches a stationary stage and yet has not disappeared completely under irradiation, it seems advisable for the cystoscopist to destroy the remnant under the guidance of the cystoscope. This seems to render the tumor more radiosensitive again, if radiation treatment is given rather promptly after the destruction.

Results of Medical Treatment of Duodenal Ulcer.—

St. John and Flood report the follow-up results of the medical treatment of 225 clinic patients whose symptoms of duodenal ulcer were severe enough to require hospitalization. Symptoms recurred in the majority of patients who were followed for

more than two years. In most instances recurrences were mild and readily controlled by further medical therapy. Approximately 75 per cent of patients were symptom free during each six months period of follow-up observation. Certain groups of patients had an unsatisfactory prognosis in comparison with other patients. The majority of patients with persistent pain lasting for more than two weeks during hospital treatment had an unsatisfactory follow-up course. When patients of this type suffered an early recurrence of symptoms after discharge from the hospital, the results were even worse. Patients who had had three or more gross hemorrhages due to duodenal ulcer were not more prone to have recurrences than the average patient in the series. When recurrence took place, however, the symptoms were more apt to be severe. Prolonged medical therapy was undertaken of a few patients with persistent pyloric obstruction. The results were unsatisfactory. The patients who were found to have a prognosis better than average were those with uncomplicated duodenal ulcer who had complete relief of pain within twenty-four hours of hospitalization and the majority of those who were hospitalized for an initial gross hemorrhage without associated pain or obstruction. The follow-up was satisfactory in these last patients.

Carbamide (Urea) Therapy in Wound Healing.—Holder and MacKay discuss the efficacy of carbamide (urea), after an experience of two years, as an adjunct to wound healing. They are still of the opinion that, although the mild bactericidal action of carbamide is of some consequence, the chief value of the compound in wound healing is due to its remarkable solvent action on protein compounds. There is some evidence that dilute urea solutions produce proliferation of capillaries by sprouting and may thus aid in wound healing. However, they prefer to avoid dilute urea solutions because of the excellent medium for bacterial growth which they provide and the superior results obtained with higher concentrations.

Vitallium for Fixation of Fractures.—Campbell and Speed used vitallium, a nonferrous alloy, in the form of plates or screws, or both, as a material for internal fixation of sixty-five various types of fractures. Its negligible electrolytic action (proved by lack of inflammation in the tissues about the plates) and the absence of absorption of bone about the screws, has made vitallium a dependable material for the fixation of fractures even in the presence of gross infection. The use of vitallium for internal fixation in infected compound fractures will prevent the spread of infection of the sequestration of devitalized portions of bone. Experimental and clinical evidence indicates that vitallium will aid in reducing these complications to a minimum and that the screws will hold the plate firmly in position, preventing displacement of the bone fragments until firm union is established.

Short Wave Diathermy in Pyogenic Infections.—Egan believes ultrashort wave diathermy is indicated for the treatment of pyogenic infections at any stage of the lesion; that it is analgesic and antispasmodic and that it can produce an intense and lasting hyperemia. The physiologic aspects of the effect of ultrashort wave diathermy on the lymphatic system have not been determined. In all his cases, without exception, when lymphangitis or lymph adenitis was associated with infections, such lymphatic manifestation disappeared with ultrashort wave therapy. This, he believes, may explain the efficacy of this therapy in facial infections because of the rich lymphatic supply of facial connective tissue.

Sulfanilamide and Sulfapyridine in Children.—Silverthorne and his co-workers state that in children sulfanilamide has reduced the mortality in streptococcal septicemia from 91 to 50 per cent and in streptococcal meningitis from 98 to 50 per cent. The drug had no effect in the treatment of eight cases of pneumococcal meningitis and questionable effect in the treatment of eight cases of influenza meningitis. Before the use of sulfanilamide the mortality in streptococcal peritonitis was 100 per cent in forty-two cases between 1923 and 1936. Of eight patients treated between 1938 and 1939 with sulfanilamide, four have recovered. In the treatment of erysipelas sulfanilamide shortens the course of the disease from seven to 1.7 days. The dosage that the authors used has been higher than that usually recommended; from 20 to 30 grains (1.3 to 2 Gm.) to 20 pounds (9 Kg.) of body weight daily. Two patients with pneumococcal meningitis have recovered after the use of sulfapyridine. The course of the disease of ten control patients with pneumococcus type I pneumonia was 8.8 days, of eleven sulfapyridine-treated six and a half days and of eleven serum-treated patients six days. Sulfapyridine has not favorably affected the course of staphylococcal infections. The authors agree with Maclean, Rogers and Fleming that "there are still fatal cases among those treated by chemotherapy, and as it is impossible to say offhand whether the infecting pneumococcus is very sensitive to sulfapyridine or not, we suggest that to obtain the best results chemotherapy should be combined with immunotherapy."

Methemoglobinemia and Sulfhemoglobinemia Due to Sulfanilamide.—Bensley and Wilén report the incidence of methemoglobinemia and sulfhemoglobinemia in 200 adults treated with sulfanilamide by mouth. Methemoglobin was diagnosed in fifty-three of the 200 cases, an incidence of 26.5 per cent. Sulfhemoglobin occurred in only two of the 200 cases, an incidence of 1 per cent. According to the authors' experience to date, there appears to be no relationship between the occurrence of these abnormal blood pigments and the tendency toward the known toxic effects of sulfanilamide; neither agranulocytosis nor acute hemolytic anemia has as yet been encountered in their hospital. A possible harmful effect of methemoglobinemia and sulfhemoglobinemia is reduction of the oxygen-carrying power of the blood. This would apply particularly to disorders which in themselves tend to cause anoxemia (pneumonia, anemia and the like). The exact cause of sulfhemoglobin formation is not known. Intestinal disease is suggested as a possible etiologic factor in the two cases cited. Data are reported which suggest a causal relationship between concentration of free sulfanilamide in the blood and the formation of methemoglobin. No such relation was found with respect to concentration of conjugated sulfanilamide. Reduction of the dosage of sulfanilamide alone reduces the degree of methemoglobinemia. When reduction is inadvisable and there is a danger of anoxemia, the latter may

be controlled by blood transfusions or, as Wendel has shown, by intravenous injection of methylene blue. To be most effective and prevent recurrence of methemoglobinemia the injections of methylene blue must be repeated approximately every eight hours. Unlike methemoglobinemia, blood transfusion is the only method known at present for the treatment of sulfhemoglobinemia.

Human Equine Encephalomyelitis.—Larimer and Wiesner state that during August and September of 1938 sixteen cases presenting features of meningitis, but with unusual spinal fluid changes, were seen in St. Joseph's Hospital. In eleven the condition was characterized by a sudden onset with headache and fever. The remaining patients had indefinite complaints of headache or fatigue for as long as seven days before calling their physician. Headache, stiff neck and a positive Kernig's sign were relatively constant, and usually pathologic reflexes were transient. Spinal fluid changes included an increase in the cell counts, especially in the lymphocyte series, normal or increased sugar content, and the absence of organisms in smears and cultures. The course characteristically was short, the fever remaining high for about five days. No relation between severity of symptoms, physical signs or spinal fluid changes and the mortality rate was noted. Cells in the spinal fluid were no more numerous in the four fatal cases than in the twelve cases in which recovery occurred. The twelve patients who recovered showed no sequelae at the time of dismissal. The histories of these cases reveal their close resemblance to epidemic encephalitis, human equine encephalomyelitis, benign lymphocytic meningitis, choriomeningitis, poliomyelitis and other conditions. Infection in more than one member of a family was not encountered. As the area from which the cases of this report came has had an epidemic of "equine encephalitis," with definite exposure to horses so affected in six of the ten reported, it has seemed probable that these cases were caused by a similar infective agent. However, the authors state that they have no proof for this impression. Treatment in these cases consisted chiefly of repeated spinal punctures and other means of reducing intracranial pressure. Fluids in amounts of from 50 to 100 cc. were given intravenously. Sulfanilamide was given an intensive trial but did not seem to alter the course of the disease. Morphine in large doses provided the best means of relief of headache. Moderately large doses of magnesium sulfate by mouth or rectum seemed to have a favorable effect. Autohemotherapy in one case seemed valueless. Convalescent serum was not tried but would deserve trial if one were sure of the diagnosis.

Chone-Chondrosternon.—Ochsner and DeBakey consider the term chone-chondrosternon preferable to the previously used terms (funnel chest, pectus excavatum, koilosternia, trichterbrust, thorax en entonnoir) describing the thoracic deformity which is usually a congenital and rarely an acquired depression of the lower portion of the sternum and the adjacent costal cartilages which become progressively more marked as the patient grows. They review the literature from the standpoint of etiology and pathogenesis and find that the most prominent congenital characteristics are heredity, growth disturbances (sternal developmental arrests, costal overgrowth, delayed sternal ossification, muscle contracture and hyperpituitarism), mediastinitis, mechanical intra-uterine compression and syphilis. The acquired factors consist of rickets, trauma and faulty posture. Chone-chondrosternon was found to occur in 0.059 per cent of a total of 46,705 persons examined. The sex incidence was found to be 78.1 per cent males and 21.8 per cent females in 268 collected cases. There are frequently no subjective or objective clinical manifestations. However, when they are present these consist of cardiac disturbances such as dyspnea, palpitation, precordial pain and in rare instances decompensation; pulmonary disturbances such as dyspnea, cyanosis, cough and diminished vital capacity; and digestive disturbances such as dysphagia and dyspepsia. In general the patients are of asthenic habitus and usually display characteristic weakness and debility. Frequently they are not resistant to infection and have a tendency toward bronchitis and tuberculosis. Treatment may be divided into conservative and operative. The conservative methods consist of breathing and postural exercises and orthopedic measures. The various operative procedures are of three types: chondrosternal resection, T sternotomy with or without costal cartilage division and traction, and sternal mobilization and costochondronal division or resection. The authors report in detail a case of the third type and describe the operative procedure employed. Examination approximately one year after operation revealed that correction of the thoracic deformity had been maintained and that the symptoms were relieved completely.

Ascorbic Acid Requirements in Peptic Ulcer.—Warren and his associates determined the ascorbic acid requirements of patients with peptic ulcer. They found that five patients with duodenal ulcer utilized 20 per cent more ascorbic acid than did normal individuals. There was no evidence that they were unable to absorb the drug when given by mouth. It was also found that these patients had been taking diets deficient in vitamin C. The usual Sippy diet contains much less vitamin C than is normally required. This deficiency can be easily compensated for by including in the daily diet the juice of one or two good sized fresh oranges.

Exclusion and Diagnosis of Typhoid.—Berger and Brecher describe a sensitive antigen suspension for use with a simple slide agglutination method which makes possible a serologic diagnosis or exclusion of typhoid without recourse to a laboratory. They employed the method on 414 serums sent to their laboratory and the procedure detected all cases with a titer of 1:80 or more, and most of those with a titer of 1:40. The method was further tested in 130 clinically observed cases, in which it gave satisfactory results. It gave a positive result in ninety-eight of 100 serums from patients with typhoid, whereas the Widal reaction gave a positive result in only sixty-eight. The intensity and rapidity of the slide agglutination reaction provide a rough measure of the titer of a serum. A quick and distinct agglutination indicates a titer of 1:80 or more and is diagnostic of typhoid. A slow and indistinct result is obtained when the titer of the serum is about 1:40. A negative test indicates with great probability that a diagnosis of typhoid may be excluded. The authors believe that the method succeeds because the nature of the suspension employed and the peculiar behavior of slide agglutinations permit the detection of O as well as H agglutinins.

Liver Necrosis Following Burns.—Belt reports cases of fatal burns which present a highly distinctive liver picture which seems on the face of it to be linked with the toxemia of burns. The hepatic damage was severe with numerous intranuclear inclusions as numerous and typical as those observed in virus diseases. Councilman lesions were much in evidence and the author states that they can hardly be regarded as true cytoplasmic inclusion bodies. Yet the lesion is something of the same order and it finds its chief association with virus diseases, namely yellow fever and Rift Valley fever. It is possibly a nonspecific cytoplasmic degeneration, but, like the nuclear

changes, sufficiently distinctive to suggest some common etiologic factor underlying its various occurrences. There was widespread midzonal necrosis producing marked disorganization of the parenchyma. The necrosis consists of hyalinization and fragmentation of liver cells. It involves the cells somewhat unevenly, sparing some altogether, affecting others only in part. There is an associated fatty change of moderate degree which gives the cytoplasm a rather moth-eaten appearance. On the basis of the present study the author believes that he can do no more than point out that the toxemia in certain cases of burns produces an effect on the liver similar to that observed in certain virus diseases and to suggest, therefore, that the noxious agent in the two instances, whatever it may be, whether virus or toxin, is of a similar character.

Bacterial Infection During Intracranial Operations.

—Cairns discusses the dangers of infection during an intracranial operation by surveying a twelve year series of major operations for intracranial tumor and allied conditions. There were 968 operations on 846 patients. There were twenty-three deaths from infection. The fatal cases included infections from *Staphylococcus albus* and *aureus*, *streptococcus*, *Diplococcus mucosus*, *Micrococcus tetragenus*, a bacillus of the Sonne type and gram-negative bacilli heretofore regarded as harmless to man. Until special measures were taken the incidence of intracranial infection increased as the operative mortality from other causes diminished. The brain itself offers considerable resistance to bacterial infection. Most fatal intracranial infections are due to inoculation of the infecting organism into the larger subarachnoid spaces or into the ventricles. Mild infections of the basal cisterns without gross pyogenic reaction can be fatal by producing adhesive meningitis. Therefore to decrease intracranial infection the following should be considered: the efficiency of sterilizing and operative technic, decreasing the bacterial content of the operating room, adequate masking of the operating personnel, administration of sulfanilamides before operation in certain cases, conservation of the blood supply of the scalp in all cases and, so far as possible, that of the arachnoid membrane in operations involving the basal cisterns.

Effect of Estrogen on Menopausal Flushes.—Murless used estrogen in the treatment of fifty-one women suffering from hot flushes incident to menopause induced by radium. In most cases treatment began between the eighth and twelfth weeks after the induced menopause. The largest daily dose of the substance was eight tablets (0.2 mg.). The patient was given four tablets daily, and the dose was increased to six or eight tablets according to the result at the end of fourteen days. After four weeks at the increased dose, if the "flushes" were sufficiently controlled, the dose was reduced to six or four tablets and finally to two. Any improvement noted was as a rule maintained and it proved unnecessary to revert to a larger dose. For control, one of every five women treated was given dummy tablets of lactose, presented in a similar packing. Although some of these said that the severity and duration of the flushes were lessened, there was no reduction of their number. A complete cure was experienced by eleven patients, the average period of treatment being about four weeks; but these were mostly patients with a small number of flushes daily, before treatment started. In only five instances did treatment fail to reduce the number of flushes and in four of these their severity was lessened.

Critical Study of Medication with Expectorants. P. Delore, Coudert and Dumont.—p. 381.

*Practical Deductions Drawn from Study of Cutaneous Reactions to Tuberculin in Course of Extrapulmonary Tuberculosis. P. Imbert and J. Martinon.—p. 389.

Tuberculin Tests in Extrapulmonary Tuberculosis.—Imbert and Martinon think that although Mozer, in a recent report on osteo-articular tuberculosis, admits that the tuberculin reactions can be employed in its diagnosis, the cutaneous reactions with tuberculin are still not given the emphasis which they deserve in the diagnosis of surgical tuberculosis. After citing some of the factors responsible for this, they say that in the more than six years that they made observations on nearly 800 subjects (children and adults) affected with or suspected of surgical tuberculosis they were able to confirm the value of cutaneous tuberculin reactions. They stress the following points: 1. In osteo-articular tuberculosis of children, if a correctly made percutaneous reaction is negative and especially if it remains negative when repeated after a suitable term, it is possible that the incriminated focus is not of a tuberculous nature. 2. In osteo-articular tuberculosis of adults, this is true in the majority of cases; in a minority it is necessary to repeat the percutaneous test two or three times. If the intradermal test with crude tuberculin must be made and if the latter test is also negative, it will be necessary to reconsider the diagnosis of active external tuberculosis and at the same time prescribe the measures which seem indicated. 3. In tuberculous peritonitis of adults, although the cutaneous reactions with tuberculin are practically always positive in the course of the serous forms and of the recently discovered forms, the authors observed with rare exception anergy in the caseous forms, in the recent ascitic but drained forms, and especially in the dry old forms the evolution of which seems terminated. 4. Certain localizations of external tuberculosis, especially adenitis and superficial articular processes, lead to manifest hyperallergy. This allergy, on the contrary, is less intense in the patients with peritonitis and in those with involvement of the knee. Further, a severe allergy outside of a recent primary infection necessitates a search for the existence of an active tuberculous focus and in the presence of a lesion makes its tuberculous origin more probable. 5. The authors do not think that irradiation with ultraviolet rays or heliotherapy plays as important a part as has been said in the tuberculin reactions. In so-called surgical tuberculosis this role is practically negligible. 6. The study of allergy, if correctly practiced, is without danger in extrapulmonary tuberculosis.

*Duodenocholedochal Reflux and Acute Necrosis of Pancreas. J. Bottin.—p. 125.

Infarct of Mesentery and of Intestine. J. Bottin.—p. 153.

Acute Necrosis of Pancreas. J. Bottin.—p. 183.

Duodenocholedochal Reflux and Acute Necrosis of Pancreas.—Bottin thinks that most pancreatitides of canalicular origin are not due to an action of the bile on the pancreas but to an action of the duodenal juice on the pancreatic gland, the juice coming in contact with the pancreas as a result of a duodenocholedochal and duodenopancreatic communication. 1. He shows that the only experimental method to reproduce acute pancreatic necrosis which sufficiently approaches the condition in human subjects is choledochopancreatic intubation by the intraduodenal route. It demonstrates that bringing the bile in contact with the excretory passages of the pancreas under conditions closely resembling those which in human subjects are said to be the cause of acute pancreatic necrosis does not provoke similar lesions. 2. Cholangiographies carried out by means of a vesical fistula show that in a relatively large number of subjects the bile can be brought into contact with the pancreas by way of the pancreatic duct without producing great damage in the gland. 3. The existence of a spasm of Oddi's sphincter has not been demonstrated as yet and the anatomic structure of this sphincter greatly reduces its significance in the choledochopancreatic reflux of the bile. On the contrary, many factors indicate the possibility of a paralysis or at least of a paresis of this sphincter. 4. The author observed various

disorders which may give rise to a paralysis or paresis of Oddi's sphincter (action of concentrated hydrochloric acid on the choledochal papilla, acute cholecystitis, acute necrosis of the pancreas, high intestinal obstruction). 5. In animals a large number of investigators demonstrated under various conditions the reality of a duodenopancreatic reflux. 6. As regards human subjects, reports increase about an ascending pathologic communication between the duodenum and the choledochal canal and even the pancreatic duct. 7. This communication seems more frequent in patients with lithiasic disorders of the extrahepatic biliary passages who have or have not undergone surgical treatment. 8. These observations tend to show that the choledochopancreatic reflux of the bile has only an accessory influence in the development of acute necroses of the pancreas which develop in patients with disorders of the extrahepatic biliary passages. The duodenocholedochal and the duodenopancreatic reflux is probably more important. 9. That the surgical treatment of biliary lithiasis certainly does not protect against acute necrosis of the pancreas is proved by the pancreatic origin of a large number of deaths following operations on the biliary passages; finally relapses of acute necrosis of the pancreas described in recent years make the influence of a duodenocholedochal reflux more probable and the influence of a reflux of bile toward the pancreatic duct less probable. 10. The duodenocholedochal reflux which, according to the author's opinion, assumes a primary role in the development of acute pancreatic necrosis in patients with disorders of the biliary passages is evidently not the only factor which intervenes in these conditions. 11. In healthy subjects, duodenocholedochal reflux is absolutely nonexistent.

Malignant Granuloma and Miliary Tuberculosis: Case. R. Pachioli.—p. 398.

*Guanidine in Blood in Diseases of Respiratory Tract in Children. A. M. Dordi.—p. 448.

Guanidine in Blood.—Dordi made determinations of the amount of guanidine in the blood of thirty-seven children with acute diseases of the respiratory tract. The method of Major and Weber, as modified by Minot and Dood, was used in the determinations, which were repeated in various phases of the disease. The author found that hyperguanidinemia is more frequent in bronchopneumonia and in purulent pleurisy than in lobar pneumonia. When hyperguanidinemia exists, it is three or four times as high as normal figures. The increase of guanidine in the blood depends exclusively on the presence of enlargement of the liver. It is probably an index of liver dysfunction in the course of the respiratory disease. Variations of guanidine in the blood parallel the evolution of the enlargement of the liver. Persistence of hyperguanidinemia after abatement of fever and of the respiratory symptoms is of a bad prognostic import.

*Blood Transfusion in Bronchopneumonia in Infants. M. J. del Carril and A. E. Largaia.—p. 1439.

Pathogenesis of Hyperthyroidism. E. B. del Castillo and J. Reforzo Membrives.—p. 1452.

Blood Transfusion in Bronchopneumonia in Infants.—Del Carril and Largaia report satisfactory results of blood transfusion in nontuberculous pneumonia and bronchopneumonia in thirty infants. In all cases a clinical and roentgenologic diagnosis of the disease had been made. Fresh 5 per thousand citrated blood was used in the majority of the cases. Preserved blood was administered only in exceptionally rare cases. The largest number of transfusions was administered through the longitudinal sinus. In rare cases transfusion was done through the jugular vein or else by the intraperitoneal route. The amount of blood which was given in each transfusion varied within 10 and 20 cc. of blood for each kilogram of body weight. Giving a transfusion slowly is of great importance. Transfusion has to be administered early in the development of the disease and repeated (if necessary) at intervals of from two to four days, up to control of the toxic and infectious symptoms. Changing donors is advisable when repeated

transfusion is necessary, to prevent possible anaphylactic accidents. Care is to be taken in selecting healthy donors (in relation to the presence of syphilis, malaria and other diseases). The authors found that transfusion controls toxic and infectious symptoms of grave nontuberculous bronchopulmonary diseases in infants, reinforces the natural organic defenses of the patients, and is excellent when it is given following proper indications and early in the development of the disease.

- *Neurohormonal Cells of the Vagus System in the Thyroid. P. Sunder-Plassmann.—p. 210.

Arteriography in Neurosurgery.—In performing arteriography Mackh employs thorium dioxide sol, which he injects with the aid of a record syringe armed with a cannula and without the intervention of a tubular system. Bilateral arteriography is only exceptionally indicated. A secondary arteriography is technically difficult. The method should be performed by the surgeon who undertakes the operation to be followed and who is willing to assume the responsibility for both. The author considers the method entirely harmless. The development of a tumor following the injection of thorium dioxide sol has not been demonstrated either in man or in animal experiments. Chemical analytic studies failed to demonstrate retention of the thorium. Fatalities developing suddenly after injection of thorium dioxide sol are not to be charged to the drug. The field of usefulness of arteriography is neurosurgery and not traumatic surgery. The method is of value in demonstrating tumors of the cerebral hemispheres. It is of no value in tumors of the posterior cranial cavity and in medially located tumors at the base of the cranium, such as those of the hypophysis, the suprasellar tumors, tumors of the third ventricle and craniopharyngomas. Arteriography is better tolerated than ventriculography and is to be preferred for patients in bad condition. An arteriogram is capable of furnishing a topographic and qualitative diagnosis of a tumor and thus renders ventriculography unnecessary. The principal indication for arteriography is for localization and recognition of the kind of tumor in the cerebral hemispheres. In the case of tumors of the temporal lobes, arteriography is indicated for the purpose of localization or when the ventricle of the involved side fails to fill in a ventriculogram. Tumors of the frontal lobes, of the temporal lobes and of the parietal and occipital regions give typical appearances of the blood vessels in arteriograms. An abnormally dilated lumen and atypical and irregular arrangement of the blood vessels suggest a malignant glioma. The diagnosis of the kind of tumor in the temporal lobes is difficult because of a comparative paucity of blood vessels. A pronounced displacement of the middle cerebral artery and of the carotid stem make it possible to diagnose a malignant glioma in this localization. Meningiomas with a parasagittal localization are recognized by the increase in the blood vessels in the corresponding portion of the falx. It is, however, necessary here to take arteriograms in two levels. The differential diagnosis of other benign tumors is largely impossible in an arteriogram. The most valuable aspect of the method is the possibility of establishing in all cases the diagnosis of a malignant glioma and thus to avoid an unnecessary operation.

Neurohormonal Cells in the Thyroid.—According to Sunder-Plassmann there exists in the thyroid a "neurohormonal" system closely associated with the thyroid follicles on the one hand and the parasympathetic portion of the vegetative nervous system on the other. This system is made up of specific cells to which the author applies the name "neurohormonal cells of the vagus system." These cells possess a large, vesicular, pale nucleus which within the follicular wall appear round and outside the follicle almost always oval. These nuclei are surrounded by a wide area of a finely granular protoplasm which imparts to the cells within the follicular wall a polygonal appearance. The neurohormonal cells are

supplied with an intraplasmatic and syncytial nervous terminal reticulum. This reticulum can be easily demonstrated in the follicular wall, in the interstitium and in the walls of the blood vessels. According to the author these cells represent the colloid-absorbing cellular system. In the resting gland these cells are found principally in the interstitium, on the periphery of the gland and in some of the follicles, to which they impart an appearance of activation. In the activated glands they are found in larger numbers in the follicular wall and exceed the colloid producing follicular cells. The author refers to the latter as thyrocytes. They possess much smaller, darker nuclei with a thick granular substance. They are arranged polygonally to one another. Their cell outlines are frequently not recognizable, suggesting that they may build a syncytium. The neurohormonal cells are seen to absorb the colloid following a unilateral section of the vagus in the neck. The previously activated thyroid glands become rich in colloid. Glands sensitized and activated by foreign protein rapidly take on the appearance of activated glands. The colloid absorbing neurohormonal cells are likewise found preponderantly in human exophthalmic goiter. They display here a thick oval nucleus when outside the follicular wall and large, pale, round nuclei within the follicle wall. The colloid producing thyrocytes predominate in diffuse colloid goiter of man. The neurohormonal cells are inactive and appear to be of little importance in endemic goiter. The author expresses the opinion that the neurohormonal cells of the vagus system are not confined to the thyroid gland but may be found anywhere in the area controlled by the vagus. This thyroid-vagus system, which may be compared to the sympathetic-adrenal system, may have important tasks to perform for the organism.

- Defects and Pseudarthroses of Bony Bridge Following Paraspinal Bone Transplantation in Growing Rabbits. G. Odelberg-Johnson.—p. 160.

Clawfoot.—Hallgrímsson's study of "idiopathic" clawfoot is based on the observations of 152 unselected patients (fifty-eight men and ninety-four women), fifty-three of whom were subjected to special attention. The age of the patients at the time when the symptoms first appeared ranged between 10 years and under and 26 years and over, most symptoms manifesting themselves between the eleventh and twentieth years. The author's purpose was to investigate the observations of others that many patients with clawfoot showed slight neurologic symptoms, mostly in the form of atrophy, slight spasticity of the lower extremities and atypical plantar response, and to ascertain roentgenologically whether these patients were afflicted with spina bifida occulta or anomalies in the lumbosacral region. Twenty-five of the fifty-three patients had spina bifida and thirty-one had neurologic symptoms, seventeen of these with spina bifida and fourteen without. According to his investigations, spina bifida can scarcely be regarded as the cause of clawfoot nor do the probabilities favor the assumption that poliomyelitis is the causative agent. Neither is the etiologic assumption of congenital myelodysplasia for clawfoot confirmed by microscopic research. Clawfoot may be the genetic offspring of lesions in certain regions of the central nervous system. The particular form of nervous disorder is difficult of detection because the early growth of clawfoot does not reveal its symptoms until the puberal and postpuberal period of life. Symptomatic treatment of clawfoot directed to the deformity and ailments of the foot, the author says, is still in the ascendancy. The author points out the advantages of peroneus transplantation over cuneiform osteotomy. The surgical intervention is small, the risk, at a minimum, and the curative process one of four weeks, equivalent to one third of the time required for recovery in osteotomic surgery. The drawback is that the disappearance of the symptoms requires from six months to one year, since the arch must have time to flatten and lengthen under the pressure of the weight of the body. Peroneus transplantation is recommended by the author in cases of slight and medium clawfoot, especially when torsion of the foot predominates.

OTITIS AND SINUSITIS IN THE SWIMMER

WITH EMPHASIS ON MAN'S LACK OF ADAPTATION
TO AN AQUATIC ENVIRONMENT

CHAIRMAN'S ADDRESS

H. MARSHALL TAYLOR, M.D.
JACKSONVILLE, FLA.

Biology is the fundamental study of the phenomena of life in all its varied relations. The biologic approach to the discussion of a medical problem is the most rational one, because man himself is a biologic study. By means of this approach the subject of immunity and resistance may be elucidated in a scientific yet not a difficult manner. The prevention of infections of the sinuses and the ear secondary to swimming illustrates this fact as well as any phase of preventive medicine. Nevertheless, in the literature pertaining to these infections the existence in man of few structural adaptations for an aquatic environment has to a large extent been ignored, and only one etiologic factor, that of contaminated water, has been extensively dealt with. My interest in other etiologic factors was stimulated by observing that a number of my patients with infections of the ear or sinuses had frequented a swimming pool fed by a spring having a flow in excess of 145,000 gallons a minute while others had used exclusively a pool with a flow in excess of 365,000 gallons a minute. Chemicals that often lead to irritation of the nasal mucous membranes were not used in either of these pools because of the low bacterial counts found in repeated examinations of the water by the Florida State Board of Health. Examination of samples collected from these pools on heavy bathing days gave results of no more than 150 bacteria per cubic centimeter, and the water showed no evidence of contamination. In other words, these patients bathed in relatively pure spring water having a temperature of 71 F., and their use of these bathing places, with their large amount of water supply and its relative degree of purity, served to emphasize the significant role of factors other than contaminated water in the etiology of infections of the ear or sinuses associated with swimming.¹

Since the dawn of civilization, public bathing places have created a problem in sanitation. Recognition of this problem antedates the Christian era. Long before

its advent the Chinese were using chemicals in their public baths, and methods of filtration were in use as early as 400 B. C. Today, advances in sanitation have kept pace with the public need for protection arising from the rapid increase in public bathing places throughout this country. The sanitary engineer has adequately solved or regulated the problems that pertain to proper construction of pools, the bacterial content and clearness of the water, the contamination of water from sputum, the diseased bather, the personal cleanliness of bathers, the laundering of bathing suits, the sanitation of the premises, and the rules for bathers before entering and while in the water. Sanitarians now give assurance that they can kill or neutralize 99 per cent of the bacteria in a pool. Furthermore, if the bathing load is kept down to 800 gallons to each bather, they consider that the pool remains in an acceptable sanitary condition.

A cogent factor in the etiology of infections of the upper part of the respiratory tract associated with swimming is man's invasion of an environment to which he is not adapted. Biologically, man derives his existence from the same ultimate sources that all other living creatures do and is subject to the same natural laws. He is a terrestrial being, adapted to his environment, but he is without important structural adaptations for an aquatic environment. This lack of anatomic and physiologic modifications is in contrast to the presence of structural adaptations in the animals whose normal habitat is water.

In all the air-breathing animals, including man, the usual stratiform flat epithelium lines the nasal vestibule and gradually assumes the structure of the stratiform ciliated cylindric epithelium, the true respiratory mucous membrane. This ciliated epithelium warms the air and keeps moist the tracts through which a current of air is constantly passing. It is designed also to secrete a mucus, both bactericidal and inhibitory to bacterial growth, that enmeshes the bacteria and carries them by its wavelike motion to the pharynx and esophagus for disposition. The difference between the upper part of the respiratory tract of man and that of the aquatic animals lies not in the mucous membrane but in the ability of animals highly modified for life in the water to close involuntarily or at will the anterior nares, an adaptation conspicuously lacking in man. They are thus able to protect the respiratory epithelium from the destructive action of water.

In every species whose normal habitat is water, some provision for excluding water from contact with the respiratory mucous membrane is found, whether in reptilian, avian or mammalian life. The alligator (*Alligator*) represents the highest form of reptilian life. The muscles of the anterior nares of this aquatic reptile are so arranged that they close the nostrils when the head

Read before the Section on Laryngology, Otolaryngology and Rhinology at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 18, 1939.

1. Taylor, H. Marshall: The Causes and Prevention of Otolaryngologic Conditions Following Swimming and Diving, *J. A. M. A.* 81: 349-351 (Aug. 4) 1923; Sinusitis and Swimming, *J. A. M. A.* 85: 7-10 (July 4) 1925; Report of Committee on Otorhinologic Hygiene of Swimming, *Tr. Sect. Laryng., Otol. & Rhin., A. M. A.*, 1936, p. 300; The Hygiene of Swimming, *Virginia M. Monthly*, to be published.

is submerged. There is a wide variation in the means by which aquatic birds protect the respiratory mucous membrane from water. The pelican (*Pelecanus*), the cormorant (*Phalacrocorax*), the snake bird (*Auhinga*) and the booby gannet (*Sula*) have no external nares. The diving petrel (*Hydrobatida*) has external nares, but they may be closed by an arrangement similar to

Fig. 1.—Nose of manatee (*Trichechus*) opened and closed. This animal, like other diving mammals, has a complicated musculature forming a sphincter in connection with a special valvular apparatus for closing the nostrils.

that in the alligator. The frigate bird (*Fregata*) has a scale-like membrane entirely closing the external nares. Though the external nares of some of the aquatic birds cannot be closed, water is not allowed to come in contact with the part of the respiratory passage that is lined by respiratory mucous membrane.

The most consistent modification of aquatic mammals for life in the water is the ability to close the external nostrils. In the Hippopotamidae, according to Howell,² the nostrils take the form of a pair of slits, closure seems to be partly voluntary and opening is accom-

Fig. 2.—Nose of hippopotamus (*Hippopotamus*) open and closed.

plished by muscular pull along both borders of the slits. Closure is accomplished in various ways, and probably no two species have exactly the same mechanism for attaining this end (figs. 1, 2 and 3).

From biology one learns that every species of animal life is adapted to its environment and that all its organs

are fitted to its functions and all its functions to its environment. But has man suitable adaptation for preventing water from entering the nasal cavity when he enters an aquatic environment by swimming or diving? What has he, or has he anything, that is homologous to the musculature that aquatic animals have for closing the nostrils and thus keeping water from the nasal cavities and their appurtenances? Anatomists agree that the compressor narium of man, that small muscle rising from the superior maxilla and inserted by an aponeurosis across the bridge of the nose into its fellow of the opposite side, is a small rudimentary muscle at best and very hard to demonstrate. With the dilator naris anterior and the dilator naris posterior, that oppose it, its function is merely to confer facial expression.

Thus lacking appropriate adaptation to an aquatic environment, man nevertheless has one natural means of protecting the mucous membrane of the nasal passages when swimming. That protection is the proper method of breathing. By exhaling through the nose while the head is submerged and inhaling through the mouth while the head is above water, the swimmer tends to

Fig. 3.—Blowhole of porpoise (*Phocaena phocaena*) closed and open.

maintain a positive air pressure in the nasal cavities and thereby protects the sinuses and eustachian tube from water. In the new strokes that require partial or complete submersion of the face and head, this method of breathing is highly important. The swimmer should take a deep inhalation through the mouth just before diving and then exhale slowly through the nose while under the water (fig. 4). The rush of water into the nasal cavities incident to diving feet foremost may readily cause acute infections of the sinuses, the middle ear and the mastoid in swimmers of all ages.

Another consistent modification that all aquatic animals have for life in the water is the ability to close the ear in order to prevent water from coming in contact with the membrana tympani. In view of this provision, in man the lack of ability to close the external ear is but another evidence of the fact that he is a terrestrial animal and does not have the modifications necessary for life in the water. As Howell² observed, it is doubtful whether any aquatic animal swims with the external auditory canals open, and when the head is submerged he is dependent entirely on bone conduction for his hearing. The alligator (*Alligator*) has, immediately behind the eye, a hinged, cornified flap that constitutes a covering for the ear. It closes tightly as the reptile

2. Howell, A. Brazier: *Aquatic Mammals, Their Adaptations to Life in the Water*, Baltimore, Charles C. Thomas, Publisher, 1930, pp. 87 and 68.

submerges. The earless seal (*Phoca*) has no pinna, and the external opening of the external auditory canal is so tightly closed that the lumen can scarcely be discerned (fig. 5). After recognizing these facts pertaining to the adaptations that aquatic animals have for protecting the drum membrane against water and realizing man's lack of like modifications, one can hardly

Fig. 4.—The diver demonstrates the correct method of breathing by exhaling through the nose while under water, as indicated by air bubbles. Positive air pressure in the nose prevents water from entering the deeper parts of the nasal cavity and gaining entrance to the eustachian tube and opening of the sinuses.

escape the conclusion that a perforation of the drum membrane is in man a positive contraindication for swimming or diving.

Otitis externa, or furunculosis, from which the swimmer often suffers, likewise illustrates that the external auditory canal was not intended to withstand the vitiating effect of water. If the hand is immersed in sterile water for thirty minutes, the skin will be wrinkled and degeneration of the epithelium will result. A similar change takes place in the ear of the swimmer or diver. Maceration of the delicate dermis by the water breaks the skin and opens up for the ever present staphylococcus an avenue of infection, with resulting furunculosis. For the valve by which the aquatic animal closes the ear, man may substitute rubber stoppers or plugs of oiled wool or cotton and thereby satisfactorily exclude water from the external auditory canal. This precautionary measure also lessens the occurrence of the various forms of otomycosis that are frequently observed during the swimming season.

Infections of the ear or sinuses secondary to swimming evidently come from one or both of the following sources: Foreign bacteria may gain entrance to the deeper portions of the nasal apparatus and the conjoined structures, or bacteria normally and constantly in this region may be allowed, by a lowered resistance on the part of the swimmer, to multiply to pathologic proportions.

Because it renders a person more susceptible to the pathogenic organisms normally harbored in the upper

air passages, lowered resistance is of paramount importance as a possible causative factor of sinusitis following swimming. A primary consideration here is the length of time one can remain in the water without reducing the temperature of the body and thus lowering resistance. Cold water has a veritable appetite for heat. The swimmer has only to dive from air of moderate temperature into water of exactly the same temperature to be reminded by the resulting chilling shock that lips get blue and teeth chatter in "temperate" water, for water takes away heat from the body twenty-seven times faster than air. It follows then that prolonged cold baths cause the body to lose heat rapidly.

The adaptations of some of the warm blooded aquatic animals for their environment and the means by which they maintain their body temperature are of interest here. Those living in cold waters are highly modified for the maintenance of a normal temperature, in their environment. The seal (*Phoca*), whether swimming, playing in the water or at rest on an ice floe, maintains a normal temperature of 101° F., and some of the cetaceans in the icy waters of the arctic have a normal temperature of 104° F. The function of keeping their bodies warm is performed by such varied means as a large liver, a thick layer of blubber, a nonconductive material and a dense kind of fat placed immediately beneath the integument. Some aquatic arctic mammalia have a heavy coat of fur as well as a fatty layer. These provisions seem to indicate that they are highly adapted mechanically to their normal habitat and that these adaptations, even in the absence of natural physiologic immunity, would adequately protect them. In man there is a conspicuous lack of such a compensating mechanism for the maintenance of a normal temperature in any medium colder than his normal surroundings. Man's loss of body heat during submersion for a period of twenty minutes at a temperature of 70° F. may be five times the normal basal rate.

My study¹ of lowered resistance from chilling in relation to infections of the ear and sinuses following swimming was previously reported before the American

Fig. 5.—Ear of seal (*Phoca*) open and closed.

Laryngological Association. In this experiment the temperatures of 250 children under 13 years of age were recorded both before and after they had been swimming for forty-five minutes in an indoor pool with the temperature of the water at 73° F. In only thirty, or 12 per cent, was a normal temperature maintained, and in all the remaining 220 there was a reduction of temperature; in some the temperature fell as low as 95° F.

In connection with my work as a member of the Committee on the Otorhinologic Hygiene of Swimming of the American Medical Association, I also previously reported my observations on a group of trained athletes and expert swimmers.¹ The eight swimmers comprising this group swam for forty-five minutes in ocean

frequenting the indoor swimming pool, where the body is not exposed to the warm rays of the sun, should be constantly active instead of following the common practice of sitting around on a cold tile floor in a cold wet bathing suit. This popular custom is as conducive to a cold as wrapping oneself in a wet blanket and sitting on the concrete floor of a basement would be. The bather who is inactive on a windy beach, where there is a rapid loss of body heat from evaporation, invites the same risk.

water at a temperature of 68.5 F. Immediately before and after this period the weight, temperature, blood pressure and blood count of each participant were ascertained. After the swim they all exhibited a diffuse generalized purplish hue and their lips and nail beds were moderately cyanotic. There was an average reduction of 4 degrees F. in the rectal temperature. The erythrocyte count was increased by from 700,000 to 1,500,000, and in the leukocyte count there was a consistent increase of from 8,000 to 10,000. The differential count indicated a normal Schilling index. Both the systolic and the diastolic blood pressure was increased, the diastolic pressure having the greater average rise, which was from twenty to thirty points (table 1). These observations led to the conclusion that prolonged chilling produces peripheral vasoconstriction, peripheral stasis and anoxemia.

It is now an accepted fact that chilling of the body surfaces causes constriction of the blood vessels of the skin and periphery that is followed by a constriction of the blood vessels of the nasal mucous membrane. Also it is generally acknowledged that prolonged ischemia of the nasal mucous membrane naturally reduces the local resistance and favors infection.

In a recent paper Dyrenforth and I² reported experiments warranting the conclusion that chilling of the body surfaces without concomitant exercise produces leukopenia, with cells of the polymorphonuclear neutrophilic type (tables 2 and 3). The application of this observation is that the child or adult, particularly when

in view of the modifications that aquatic animals have for their environment, i. e. for preventing water from gaining entrance into the upper part of the respiratory tract and into the external auditory canal and for maintaining a normal body temperature in cold water, provisions that man is conspicuously without, there is but one conclusion: that man is essentially a terrestrial animal and that his anatomy and physiology are not modified for an aquatic environment. When out of his normal sphere, unless he takes cognizance of the limitations nature has placed on him and heeds the fundamental laws that regulate his being, he subjects himself to the likelihood of contracting the infections that frequently beset the swimmer. These nasal and aural involvements run the gamut of pathologic conditions from the innocent circumscribed furuncle to a disease condition of the

Branches of Medical Research.—A statement that medicine is founded on physiology is, as has been said, but a fraction of the truth. There are vital branches of clinical knowledge to which physiology contributes little if at all. There are three chief ways in which clinical progress is achieved, and these may be reviewed briefly. They are (a) the discovery of disease, that is the identification of disease and its natural history; (b) experimental work on clinical cases; and (c) the application of physiological ideas and discoveries.—Lewis, Sir Thomas: *Research in Medicine and Other Addresses*, London, H. K. Lewis & Co., Ltd., 1939.

THE DIAGNOSIS AND TREATMENT OF HYPERTHYROIDISM ASSOCIATED WITH PREGNANCY

BERNARD PORTIS, M.D., Ph.D.

Attending Surgeon, Michael Reese and Cook County Hospitals
AND

HAROLD A. ROTH, M.D.

Associate Surgeon, Cook County Hospital
CHICAGO

Hyperthyroidism associated with pregnancy may give rise to considerable anxiety as to the well being of the mother and the satisfactory continuation of gestation. The features which require critical analysis are the increased physiologic activity of the thyroid gland during pregnancy and the possible variations in the clinical syndrome of thyrotoxicosis. This presentation will attempt to clarify the various issues. We were permitted to review the records of 1,000 patients of the obstetric department of the Michael Reese Hospital; included also are observations on 500 patients subjected to thyroidectomy in the charity surgical service.

The thyroid gland shows various changes during normal pregnancy. Research with human beings and animals directed toward determining the underlying cause has demonstrated the stimulatory effects on the thyroid by the thyrotropic hormone of the anterior pituitary gland. This has been well established by the investigations of Marine,¹ Collip, Selye, Thomson and Williamson,² Loeb and Bassett,³ Anderson and Collip,⁴ Anselmino and Hoffmann⁵ and Soule.⁶ There is some enlargement of the thyroid gland in the majority of patients. We found this present in about 31 per cent of pregnant women, with more constant appearance in subsequent child-bearing periods. Several authors have commented on the presence of hyperplasia of the glandular elements with increased vascularity.

The clinical manifestations referable to the thyroid in normal pregnancy were few. There was frequently an associated nervous instability which simulated hyperthyroidism; however, the accepted physical and laboratory signs were conspicuously absent. Pressure symptoms have been reported and were due to the excessive size of the gland. Recognition of the accepted progressive gain in weight and the normal variations in the basal metabolic rate during pregnancy were helpful in differentiating the physiologic from the pathologic states.

Frequent observations of the basal metabolic rate during pregnancy have been enlightening. Baer⁸ in 1921 made one of the earliest contributions to this study. His results showed an elevation of the rate to an average of from +33 to +35 per cent for forty-four normal

women in the last trimester of pregnancy. Subsequent investigations by Sandiford and Wheeler,⁹ Plass and Yoakam,¹⁰ Windfeld,¹¹ Hanna¹² and Hughes¹³ confirmed this observation. Further, it was noted that it was usual to register a normal basal rate during the first five months of gestation with an increase of from 15 to 25 per cent later. Due consideration of this fact was important in utilizing the rate as a criterion of thyrotoxicosis.

The incidence of hyperthyroidism as reported in the literature varied according to whether it was recorded by a surgeon or an obstetrician. The surgical reports by Mussey, Plummer and Boothby¹⁴ and Clute and Daniels¹⁵ showed that about 0.5 per cent of the total number of women subjected to thyroidectomy were pregnant. However, Bram,¹⁶ Yoakam,¹⁷ Frazier and Ulrich,¹⁸ Gardiner-Hill¹⁹ and Fahrni,²⁰ writing from the obstetric point of view, noted thyrotoxicosis in about 3 per cent of a large series of pregnant women. We encountered hyperthyroidism in 1.4 per cent of 1,000 pregnant women and an incidence of pregnancy in 500 patients subjected to thyroidectomy of 0.4 per cent.

The symptoms of established hyperthyroidism were similar when associated with pregnancy and in the non-pregnant state. However, the subsequent clinical course in some cases showed distinct variations from the usual progressive nature of the disease. This feature was of extreme importance in the decision as to the appropriate therapy. Mussey, Plummer and Boothby¹⁴ maintained that pregnancy did not influence the course of exophthalmic goiter. However, Clute and Daniels¹⁵ said that the existence of pregnancy was a serious burden to the patient with thyroid disease. Falls²¹ drew special attention to the important observation that hyperthyroidism might become worse or be ameliorated as pregnancy continued. Küstner²² and Seitz²³ also declared that this fact was important for a complete understanding and evaluation of the problem.

Our series consisted of fourteen patients in a total of 1,000 pregnant women from the obstetric service of the Michael Reese Hospital. An analysis of their cases revealed that the average age was 31 years and the average duration of pregnancy when the patient was first observed was five months. Four women were primiparas and ten were multiparas, and in the latter group the average number of previous pregnancies was three. Further, five of these patients gave a history of hyperthyroid manifestations in earlier pregnancies. The

HYPERTHYROIDISM—PORTIS AND ROTH

896

essential symptoms were nervousness, palpitation, weakness, intolerance to heat and an average loss of weight of 5 pounds (2.3 Kg.). The physical signs were those of enlargement of the thyroid gland in all the patients, the enlargement being nodular in six and diffuse in eight. Tremor was uniformly present, but the ocular signs were positive in only seven. The pulse rate was about 94 and the average blood pressure was 138 systolic, 86 diastolic. The mean basal metabolic rate was +35.8 per cent. Ten of the patients were carried to term by conservative measures. Two required thyroidectomy. One was delivered of a still born fetus at term, and the fourteenth had an induced abortion at the third month. The two patients who were subjected to thyroidectomy and the one who had an abortion will be considered in detail:

CASE 1.—Mrs. M. D., aged 36, a quintipara, first seen in the thyroid clinic April 16, 1937, was then two months pregnant. She complained of nervousness, palpitation, weakness and difficulty in breathing and swallowing. The examination showed marked enlargement of the thyroid, a pulse rate of 90, tremor of the hands, negative ocular signs and a basal metabolic rate of +39 per cent. Compound solution of iodine caused decided improvement. She was operated on May 17 by Dr. D. C. Straus. The tissue removed weighed 500 Gm. and showed evidence of a nodular colloid goiter with hyperplasia of the glandular elements. Her convalescence was uneventful and she was delivered normally in December 1937.

CASE 2.—Mrs. R. S., aged 34, a tertipara, first seen in the thyroid clinic Jan. 8, 1937, was then four months pregnant. Her complaints were marked nervousness, irritability, palpitation, weakness, fatigue and intolerance to heat. Similar symptoms had been present in her preceding pregnancy but had subsided, with reappearance in the second month of the present gestation. They were consistent with a severe grade of thyrotoxicosis and with the basal metabolic rate of +58 per cent. Operation was advised but she did not return for a month, at which time her condition was much aggravated. She had lost 5 pounds (2.3 Kg.), and her basal metabolic rate was +110 per cent. Her urine now contained albumin, and the electrocardiogram showed marked myocardial disease. An x-ray examination revealed a large substernal thyroid. We considered her condition as an early thyroid crisis. She was put at complete bed rest in the hospital and given compound solution of iodine and the basal metabolic rate dropped to condition improved and the first operation (B. P.) was +50 per cent in ten days. The first operation (B. P.) was performed February 19 with evipal, rectal and local anesthesia. At this time a right hemithyroidectomy was performed and the excised gland weighed 90 Gm. Her convalescence was uneventful, with the continuance of the same preoperative measures. Her basal metabolic rate decreased to +35 per cent. The remaining left lobe and isthmus of the thyroid were removed March 12. Her entire clinical picture cleared up. She was delivered of a normal child June 13. Later follow-up showed that she was in excellent health and had a normal basal metabolic rate.

CASE 3.—Mrs. J. M., aged 30, first seen in the thyroid clinic Oct. 8, 1937, manifested symptoms of severe thyrotoxicosis. She had noticed the goiter for about seven years, but there were few symptoms until after her first pregnancy, with twins, a year previously. The interval was one of great nervous strain, as one of the twins was in poor economic condition. On examination the thyroid was markedly enlarged, the pulse rate was rapid and the blood pressure was 134 systolic, 70 diastolic. The ocular signs were positive. The basal metabolic rate was +72 per cent. Preoperative preparation with compound solution of iodine was started and there was some improvement. At operation by Dr. D. C. Straus, October 29, she suddenly underwent a severe reaction, so that only a bipolar ligation was performed. The immediate postoperative course was very stormy but she gradually rallied and improved. Three weeks later a right hemithyroidectomy was performed (B. P.)

and again her condition was critical for several days. However, there was steady improvement, with a gain of 8 pounds (3.6 Kg.), and the basal rate was reduced to +22 per cent. She was again admitted to the hospital, and December 16 the third operation was performed. At this time the left lobe could be only partially removed because of excessive adhesions to the jugular vein, a result of the first operative procedure. Her subsequent follow-up showed a steady gain in weight of 17 pounds (7.7 Kg.) and a basal rate of +16 per cent. We were well satisfied with her condition, but on June 10, 1938, she came to see us with further evidence of thyrotoxicosis and, in addition, she was three months pregnant. Her basal metabolic rate was +57 per cent. Consultation with the obstetricians and internists was held and, after considering the many factors already described, we decided to have an abortion and sterilization carried out. This was done on June 27. She is now in good general health.

In all these cases the diagnosis was obvious and did not present any unusual problems. There were, however, many instances in which we could not immediately arrive at a definite conclusion. The most perplexing issues were the evaluation of physiologic hyperactivity of the thyroid gland which accompanies normal pregnancy and the associated nervous instability. We frequently requested a period of observation before deciding on a procedure. The differential diagnosis included various neurasthenic states, toxemias of pregnancy and various systemic diseases. The accepted symptoms, physical evidence and results of laboratory tests for thyrotoxicosis usually sufficed in establishing the diagnosis.

The treatment of hyperthyroidism associated with pregnancy frequently gave rise to considerable variation of opinions as to the most suitable procedures. Generalizations, as a routine, were not advisable, as is generally accepted in thyrotoxicosis in the nonpregnant patient. It must be borne in mind that in many pregnant patients the hyperthyroidism remains more or less stationary; in some the symptoms become aggravated and finally, in a few instances, an actual amelioration occurs. Hence we frequently advised a period of observation of from one to several months in order to determine the final clinical pattern with reference to the prophylaxis and active treatment of hyperthyroidism associated with pregnancy warrants careful analysis before one draws definite conclusions.

Many prophylactic measures have been advised. Bloss²⁴ emphasized the necessity of careful antepartum observation relative to the status of thyroid activity in order to institute corrective therapy at an early date. Crotti²⁵ advised against marriage in the presence of exophthalmic goiter and said that when marriage had taken place thyroidectomy should be carried out before pregnancy was contemplated.

The use of iodine as a prophylactic measure merits careful consideration. Marine²⁶ found that there was an iodine deficiency during pregnancy and that even minute amounts of iodine usually prevented or controlled thyroid enlargements. Further, Marine²⁷ found that 2 Gm. of sodium iodide or its equivalent, if given during the first half of pregnancy, prevented thyroid enlargement in both the mother and the fetus. Yoakam²⁸ was not able to substantiate this with constant uniformity but found the use of iodine effective in preventing

further changes in glands already the site of pathologic processes. Davis²⁸ advised the use of 5 drops of syrup of hydriodic acid every other day during pregnancy or, if preferred, an iodostarine tablet three times a week. Stein (personal communication) has used iodine for many years with excellent results. His plan is to give 2 drops of saturated solution of sodium iodide daily for one month in the first trimester. Mussey²⁹ stated that the amount of iodine normally ingested was frequently insufficient to meet the requirements of the pregnant woman.

The literature concerning the active treatment of hyperthyroidism is extensive and controversial. Again there is a divergence of opinions between the obstetrician and the surgeon.

Crotti²⁵ in 1918 made several statements which are still pertinent to the subject. He concluded that the majority of patients, if they observed a careful regimen, could be brought to term without any serious disturbances. However, if the thyrotoxic symptoms progressed so as to endanger either the mother or the child, then a thyroidectomy was the ideal procedure. Mussey, Plummer and Boothby,¹⁴ Clute and Daniels,¹⁵ Lehman,³⁰ Fahrni²⁰ and Bothe³¹ have advised thyroidectomy in the majority of cases of pregnancy and have said that this procedure was essential in the treatment of hyperthyroidism associated with pregnancy. Means³² stated that it was the thyrotoxicosis and not the pregnancy which should be interrupted. Mussey²⁹ advised thyroidectomy in all cases except in the last six weeks of gestation, and even then if the patient had suffered visceral damage due to the thyrotoxicosis he felt that abortion was definitely contraindicated, as it might precipitate a thyroid crisis. Hinton³³ said that abortion was the method of choice if the patient was seen early in pregnancy with moderately severe thyrotoxicosis. Falls,²¹ Yoakam,¹⁷ Hinton,³⁴ Fleischer,³⁵ Wallace³⁶ and Rhind³⁷ concluded that the majority of patients with hyperthyroidism complicating pregnancy could be carried to term by conservative measures. Strouse and Daly³⁸ found that periodic use of compound solution of iodine was effective in persons who manifested symptoms of hyperthyroidism in pregnancy.

SUMMARY

The thyroid gland undergoes physiologic and morphologic changes during the course of pregnancy. Clinical and animal research have definitely established the active participation of the thyrotropic hormone of the anterior pituitary gland as an etiologic factor in the increased thyroid activity. Enlargement of the gland was found in about 30 per cent of all the pregnant women.

The symptoms referable to the physiologic changes in the thyroid gland were few except in the rare case in which pressure manifestations were caused by its excessive size. However, it was not uncommon for patients to present symptoms which simulated those of hyperthyroidism. The basal metabolic rate usually remained normal until the last trimester of pregnancy, when it increased to from +20 to +25 per cent. Recent investigations relative to the iodine concentration in the blood have revealed it to be increased in pregnancy.

Hyperthyroidism associated with pregnancy was comparatively infrequent. The reports from the surgical and obstetric clinics showed extreme variations. The surgical clinics reported an incidence of pregnancy of about 0.5 per cent for the total number of thyroidec-tomies, whereas the obstetric services found hyperthyroidism in about 3 per cent of all pregnant women. It seemed most logical that the true observations should be based on the reports of the obstetricians in order to decide more accurately the diagnostic criteria and therapeutic indications.

The diagnostic features of hyperthyroidism associated with pregnancy were for all intents and purposes identical with those of hyperthyroidism in the nonpregnant state. But the subsequent course frequently assumed a different clinical pattern from that of ordinary hyperthyroidism. It was essential to realize that the accepted progressive nature of thyrotoxicosis was frequently altered during pregnancy. The majority of the patients showed either a stationary condition or an amelioration, and only a small number showed progression as gestation continued. Hence it was considered justifiable to observe the individual case for from one to several months so as to determine the final severity of the thyroid disease. Particular attention was placed on the weight, pulse rate, blood pressure and repeated determinations of the basal metabolic rate. The patients who showed progression of the thyrotoxic process failed to gain according to the accepted weight curve of pregnancy and many lost weight. Further, the basal metabolism showed more marked elevation than that expected because of the physiologic variation already mentioned. Finally, the general condition of the patient showed increasing nervousness, irritability and weakness.

The prophylactic treatment must take into consideration the avoidance of pregnancy by patients who have evidence of hyperthyroidism or who have manifested thyrotoxic symptoms in previous pregnancies. Antepartum observations of thyroid activity have frequently been helpful in preventing a progression of the disease. The use of iodine early in pregnancy appears well founded, as its use has reduced the incidence of hyperthyroidism.

The active treatment of hyperthyroidism complicating pregnancy has been satisfactory and established. The essential factor depended on the final clinical pattern which the thyrotoxicosis assumed. The conservative methods of treatment, which consisted of adequate rest, sedation and hygienic measures, were sufficient in the majority of cases. Compound solution of iodine was frequently advisable as an additional therapeutic agent, but it had to be used judiciously so as not to obscure the progressive character of the disease in some cases. Further, its use might render a patient iodine resistant if surgical intervention was later decided on.

Thyroidectomy was necessary for the smaller group of patients, in whom the thyrotoxicosis showed increas-

ing severity, with visceral damage. The period of pregnancy was not the determining factor; however, operation was only occasionally advised in the last trimester. The accepted preoperative treatment with compound solution of iodine and single or stage operations were the accepted procedures, as was the case with thyroid operations in general.

Interruption of pregnancy is contraindicated except under unusual circumstances. Some authors, however, still consider that abortion is indicated if the patient is seen in the first trimester and the thyrotoxicosis is mild. Several instances have been reported of thyroid crisis precipitated by such procedures.

CONCLUSIONS

Eleven of the fourteen patients with thyrotoxicosis were treated by conservative measures and were delivered normally at term. Two required thyroidectomy in the third and the fifth month respectively. The first patient was operated on in one stage and the second patient required a two stage procedure. Both of these patients were delivered normally at term.

The final patient was subjected to an abortion and sterilization in the third month, as the previous history of thyroid disease and multiple operations precluded the likelihood of further successful operation for the thyroid. The social and economic status of the patient also influenced us in this decision.

104 South Michigan Avenue.

ABSTRACT OF DISCUSSION

DR. ROBERT D. MUSSEY, Rochester, Minn.: The authors reported fourteen instances of hyperthyroidism among 1,000 pregnant women. The mean basal metabolic rate of 35.8 per cent which obtained in this group indicates a mild average degree of hyperthyroidism. Among the twenty-five patients with hyperthyroidism complicating pregnancy observed at the Mayo Clinic during the eight years ended December 1936, seven consulted us for obstetric care and eighteen came primarily because of the hyperthyroidism. The average degree of hyperthyroidism in the latter group was decidedly more severe than in the former group. In the authors' fourteen cases the enlargement of the thyroid gland was nodular in six and diffuse in eight. This descriptive finding merits further discussion. There are two distinct disease conditions of the thyroid gland associated with hyperthyroidism. One, exophthalmic goiter, is characterized by a diffuse hyperplasia of the thyroid gland. The other type of hyperthyroidism is that which may be associated with toxic nodular or adenomatous goiter. The course of exophthalmic goiter in the nonpregnant woman is subject to considerable fluctuation. Remissions are not uncommon; complete spontaneous recovery may occasionally follow a remission. A remission is usually followed by an exacerbation, which may be progressive and may proceed to a state of thyroid crisis from which a patient may not recover. Similar characteristics obtain during the course of exophthalmic goiter associated with pregnancy, with the possible exception that the pregnant woman may sometimes tolerate hyperthyroidism better than the nonpregnant woman. Of the twenty-five patients previously mentioned, fourteen had exophthalmic goiter. All of these patients received compound solution of iodine in addition to sedative measures; seven were carried to the termination of pregnancy without operation. Several of the latter group were patients who had previously been operated on for severe exophthalmic goiter and the condition had recurred during pregnancy. In contrast to the fluctuations which often occur in the course of exophthalmic goiter, the course of hyperthyroidism associated with thyroid adenomas usually is progressively worse. Persistent hyperthyroidism, even when comparatively mild, may insidiously cause cardiac degeneration. The benefit derived from the administration of iodine to patients with hyperfunctioning adenomatous goiter is not consistent and is often transient at best. In the presence of large multiple adenomas a hazard occurs owing to

the pressure of substernal masses on the trachea. Because of the conditions which have been mentioned, nearly all pregnant women with hyperfunctioning adenomatous goiter are advised to have the adenomas removed without undue delay. Interruption of pregnancy does not cure hyperthyroidism, which must be treated in any event. In seriously ill patients a hyperthyroid crisis is liable to be precipitated when any surgical procedure is attempted before the disease is under control. Therapeutic abortion may be indicated in rare instances, but on the whole I agree with what the authors have said, and with Means, that the hyperthyroidism should be interrupted rather than the pregnancy.

DR. BERNARD PORTIS, Chicago: We as surgeons are deeply interested in thyroid disease as a whole, and it has been our good fortune to see a variety of complicated thyroid states. One has been the question of pregnancy, and we have watched these patients in our antepartum, thyroid and surgical clinics. Everything that Dr. Mussey has said I agree with. The purpose of presenting this paper was to bring to attention again the necessity of individualizing this entire clinical syndrome so that each patient may have the proper therapy instituted at the correct time; it should not be grouped in the general category of hyperthyroidism. There are many additional factors, chiefly physiologic reactions occurring during pregnancy, which may alter the clinical picture.

THE CLINICAL IMPORTANCE OF INFECTION OF THE RESPIRATORY TRACT IN RHEUMATIC FEVER

T. DUCKETT JONES, M.D.

AND

JOHN R. MOTE, M.D.

BOSTON

The clinical association of infections of the upper respiratory tract with the precipitation of attacks of rheumatic fever has received attention for many years. More recently, the reports of Coburn and his co-workers¹ have stressed the importance of the invasion of the respiratory tract by the hemolytic streptococcus in infections of the upper respiratory tract associated with rheumatic fever. This relation between hemolytic streptococcus tonsillitis or pharyngitis and recurrent rheumatic fever is familiar to the majority of the students of the disease. On the other hand, Wilson and her co-workers² state that, "while the occurrence of respiratory infections in a rheumatic child may not be a fortuitous event, it would seem to bear no more specific etiological relationship to rheumatic disease than would be attributed to similar episodes occurring in the tuberculous child."

The data to be discussed are the clinical portion of the results of a large laboratory and clinical study that was undertaken in an attempt to evaluate the importance of infections of the respiratory tract in rheumatic fever and especially the role of the hemolytic streptococcus in rheumatic and nonrheumatic infections. The immunologic data of this study are to be presented else-

where and will be only briefly mentioned in this report when they clarify certain clinical points under consideration.

The great majority of the data to be presented were collected from clinically observing 749 patients with rheumatic fever for approximately one year, from December 1934 to December 1935, but there are included some observations relating to infections of the respiratory tract and recurrences in subjects with rheumatic fever under observation in the House of the Good Samaritan prior to this time. In the analysis of the data collected, the patients with rheumatic fever were divided into those who were clinically in their first attack of rheumatic fever and those known to be rheumatic fever subjects and not in their first attack of the disease. The data on the latter were further separated into those relating to infections of the respiratory tract or recurrences in subjects with active rheumatic infection at the time. The latter data are omitted from the present discussion because of the controversial nature of both the clinical evaluations and the interpretation of the laboratory evidence. Clinically it may be said that, once the rheumatic process is activated, the disease may vary in its severity either in association with or independent of precipitating events; therefore the relation of precipitating events and the "recurrences" in these subjects with active rheumatic fever is not sufficiently clear to allow for detailed analyses of the data. However, it is our clinical impression that, in the active phase, the disease may increase in severity as a result of mild events which are usually not followed by recurrences in patients in the inactive stage of the disease.

CULTURE STUDIES OF MATERIAL FROM
THE THROAT

In diagnosing and studying infections of the respiratory tract, it is a common practice to culture material from the throat as an added check on the clinical diagnosis, and in many instances great reliance is placed on the bacteriologic result. Because of this, it was considered worth while to study the incidence of hemolytic streptococci in the throats of both rheumatic and non-rheumatic children during the year of our study, because we were also collecting serologic data which constituted some check on the significance of the bacteriologic data. Further studies of ours in other years as well as the results of other workers indicate that the incidence of hemolytic streptococci in the throats of both normal and sick persons varies from year to year. However, the results of cultures in the year 1935, which concern both rheumatic and nonrheumatic children living under different environmental conditions, are considered sufficiently interesting to present.

Swabs of material from both tonsillar fauces and the pharynx were cultured by streaking on 10 per cent horse blood nutrient, proteose-peptone, beef infusion phosphate buffered and 0.3 per cent dextrose agar. Cultures were considered positive only if there was an appreciable number of colonies (ten or more) that were further identified by microscopic examination but were not otherwise typed.

An examination of the accompanying table reveals that five groups were examined, so far as possible at monthly intervals, throughout the first eight months of the year 1935. In the first group of hospitalized subjects with rheumatic fever the incidence of hemolytic streptococci

was appreciable, whereas for the ambulatory rheumatic patients living at home (group 2) the incidence was in all instances lower. In contrast to the percentages noted for the first two groups, the incidence of hemolytic streptococci in a stationary group of hospitalized non-rheumatic children (group 3) was very high; but it should be noted that the incidence of these organisms in this group in the previous month was only 8 per cent, and an epidemic of streptococcal infections began in January and lasted through February. The results in the successive months in this group indicate the slow disappearance of these organisms in an infected stable population unit.

The data on group 4, children living in very close contact either because of crowded conditions or because of their habits, suggests that, even in the absence of an epidemic of frank hemolytic streptococcus infections, once this organism is introduced into such a group it may remain for months.

Group 5 consisted of apparently healthy children living at home but having a history of frequent infections

Incidence of Hemolytic Streptococci in Five Groups of Patients

	Group 1: 183 Hospitalized Children with Rheumatic Fever		Group 2: 351 Ambulatory Children with Rheumatic Fever		Group 3: 94 Hospitalized Children Without Rheumatic Fever		Group 4: 332 Children in Institutions		Group 5: 459 Children with Frequent Infections of Upper Respiratory Tract	
Month	Cultures	Percentage Positive	Cultures	Percentage Positive	Cultures	Percentage Positive	Cultures	Percentage Positive	Cultures	Percentage Positive
January....	98	16.3	113	13.3	114	41.3	235	49.9	267	20.2

Total....	663	23.0	744	13.0	708	23.2	742	46.4	477	23.0

of the respiratory tract. For the two months in which significant numbers of cultures were obtained, the results are quite comparable to those of the ambulatory rheumatic children living at home.

This table merely expresses the carrier rate of the hemolytic streptococcus in several groups of children and emphasizes that a bacteriologic culture of material from the throat is of little value, in itself, in differentiating infections of the upper respiratory tract in children. The effect of an epidemic of streptococcal infections on the carrier rate of a stable population unit is well shown, and in the absence of an epidemic of frank streptococcal infection the effect of close environmental contact on the carrier rate of a stable population unit is well illustrated by the data presented.

CLINICAL CRITERIA

Definition of First Attack of Rheumatic Fever.—It is often difficult to be certain of the actual onset of rheumatic fever. The patients classified in this series as having a first attack were included only when we could be relatively certain that the illness under consideration was the initial episode of rheumatic fever. The majority of such illnesses were rather severe and occurred in patients who had been well in the relatively recent past and had no previous history of rheumatic fever and no recognized rheumatic heart disease prior to the illness.

Definition of Severity of Rheumatic Fever.—In this report the severity of the activity of rheumatic fever is indicated as follows: +++, severe or fulminating rheumatic fever; ++, moderately severe rheumatic fever as indicated by frank clinical and laboratory evidence (corrected sedimentation rate, white blood count, electrocardiographic changes) of infection; +, mild

rheumatic fever as indicated by mild clinical manifestations in first attacks or mild clinical or laboratory evidence of infection in recurrences. Chorea in the absence of other rheumatic manifestations is included in this classification.

Definition of Infections of the Respiratory Tract.—The classification of sore throats and colds in this study is based entirely on the clinical symptoms as given by the patient:

Cold: An infection of the upper respiratory tract in the absence of symptoms of a sore throat are considered to be colds. Any cold having the associated symptom of a sore throat is considered to be a sore throat.

Sore Throat: The designation of a sore throat is dependent only on the clinical symptoms of a sore throat.

Chart 1.—Clinical analysis of first attacks of rheumatic fever in relation to the severity of the attack and the preceding events. Included in the total but not otherwise shown are nine first attacks that were clinically associated with infections or traumas outside the respiratory tract.

No attempt has been made to divide the sore throats or colds on the basis of their severity in relation to the subsequent rheumatic fever.

FIRST ATTACKS OF RHEUMATIC FEVER

In chart 1 are data concerning 160 first attacks of rheumatic fever considered in relation to the severity of the attacks and also in reference to the precipitating events clinically associated with the attacks.

As shown in this chart, nearly 60 per cent of the first attacks represented severe illnesses. Of the sixty-one

Chart 2.—Respiratory infections (512) in subjects with inactive rheumatic fever. The black columns indicate recurrent rheumatic fever subsequent to the infection of the respiratory tract. The white columns indicate absence of recurrences subsequent to the infection.

first attacks of rheumatic fever that were preceded by the clinical symptoms of a sore throat, 75 per cent were severe illnesses, whereas the incidence of severe attacks associated with colds was less, 55 per cent. Further analysis of the data has shown that one half (49 per cent) of the severe first attacks were associated with sore

were fifty-nine first attacks (37 per cent of the attacks under consideration) the subject of which was entirely well, so far as the history indicated, until the onset of the rheumatic fever. Such attacks are important in a discussion of the role of infection of the respiratory tract in precipitating rheumatic fever, and it is significant to examine the patients with regard to a possible dissociation between hemolytic streptococcus infections and rheumatic fever. When the immunologic data³ were examined in twenty-three of the cases in which there were adequate serologic studies, it was found that the incidence of hemolytic streptococcus antibodies was as high in this group as in the two groups with associated infections of the respiratory tract. Furthermore, the incidence of these antibodies in all the first attacks that were immunologically studied was comparable to their incidence in association with other hemolytic streptococcus infections. These observations are interpreted

Chart 3.—Relation of the duration of the inactive phase of the rheumatic infection to the precipitation of recurrences after infections of the respiratory tract.

to indicate that even in the absence of the clinical symptoms of an infection of the respiratory tract most first attacks of rheumatic fever are associated with hemolytic streptococcus infections.

INFECTIONS OF RESPIRATORY TRACT IN SUBJECTS WITH INACTIVE RHEUMATIC FEVER

We have discussed the close association between infections of the respiratory tract and hemolytic streptococcus infections and the precipitation of first attacks of rheumatic fever. It is therefore most interesting to investigate the significance of these infections in precipitating recurrences of rheumatic fever in known rheumatic subjects in the inactive phase of the disease. Among such subjects, 512 infections of the respiratory tract were observed and followed in relation to a possible subsequent recurrence. In chart 2 are shown the data on these infections, of which 180 were clinical sore throats and 332 were symptomatic common colds without associated sore throat. An examination of the data relating to the sore throats indicates that nearly one half (47

3. Mote, John R., and Jones, T. Duckett: Data to be published.

per cent) of the symptomatic sore throats were followed by recurrences of rheumatic fever within three or four weeks. On the other hand, chart 2 shows that less than a third (29 per cent) of the clinical colds were followed by recurrences of rheumatic fever.

In chart 3 the same data are presented in relation to the duration of the inactive phase of the rheumatic

Chart 4.—Age of the patients at the time of the infection of the respiratory tract; the black columns indicate recurrent rheumatic fever.

infection prior to the infection of the respiratory tract under consideration. An examination of the data in this chart suggests that in a subject with inactive rheumatic fever the chance of a recurrence following an infection of the respiratory tract decreases as the duration of the period of inactivity increases.

The same clinical data are analyzed in chart 4 in relation to the age of the patient at the time of the infection of the respiratory tract under consideration. The chart indicates that except for patients from 16 to 20 years old there is about a 50 per cent chance that rheumatic fever will recur subsequent to a clinical sore throat, regardless of the age of the patient at the time. Except for the same patients, there is about a two to one chance that it will not recur after the symptoms of the common cold, regardless of the age of the patient at the time. There is yet no obvious explanation for the relative immunity to a recurrence following infections of the respiratory tract of patients from 16 to 20.

RECURRENCES OF RHEUMATIC FEVER IN SUBJECTS WITH INACTIVE RHEUMATIC FEVER

The 271 recurrences of rheumatic fever observed in patients with inactive rheumatic fever have been analyzed in chart 5 in relation to the severity of the recurrence and according to the type of precipitating event that preceded the recurrence. An examination of the data suggests that the incidence of severe illnesses (40 per cent) is not as great as for the first attacks (58 per cent). It is interesting to note that half (49 per cent) of the attacks associated with sore throats were severe illnesses, whereas only a third (34 per cent) of the recurrences associated with the common cold were severe. As in the case of first attacks of rheumatic fever, seventy-eight recurrences (29 per cent of the 271 recurrences under consideration) were observed clinically to be unrelated to any preceding infection of the respiratory tract or other episode. These attacks represent apparently spontaneous recurrences of rheumatic fever in patients in the inactive phase of the disease. Such patients also form an important group in a consideration of the role of both infections of the respira-

tory tract and hemolytic streptococcus infections in the causation of rheumatic fever, since they represent an apparent dissociation between the former two conditions and the latter in known rheumatic subjects. Consequently, the immunologic data on all of the recurrences in which there were adequate serologic results were analyzed in detail. From this analysis, which will be presented in detail elsewhere,³ it is evident that the hemolytic streptococcus is an important precipitating agent in the severe recurrences of the evidence also suggests that mild or even moderately severe attacks of rheumatic fever may occur either in association with or independent of infections of the respiratory tract and without any detectable serologic evidence of an associated hemolytic streptococcus infection.

SUMMARY AND CONCLUSIONS

It is evident, according to our experience, that a close relationship exists between acute infections of the upper respiratory tract and the first attacks of rheumatic fever and recurrent rheumatic fever as well.

Infections of the respiratory tract preceded 58 per cent of the first attacks of rheumatic fever, and of these precipitating infections two thirds (66 per cent) were symptomatic sore throats. On the other hand, more than one third (37 per cent) of the first attacks were apparently clinically spontaneous attacks of rheumatic fever. However, serologic evidence indicates that a hemolytic streptococcus infection was associated with most of the first attacks of rheumatic fever, whether or not there were preceding symptoms involving the respiratory tract.

In patients in the inactive stage of rheumatic fever, sore throats and colds commonly precipitate recurrent

rheumatic fever. In such patients sore throats are followed by recurrent rheumatic fever in approximately one half of the instances, and almost one third of the colds are followed by recurrent rheumatic fever. In general, regardless of the age of the patient, the chance of a recurrence subsequent to an infection of the respiratory tract decreases as the period of the inactive phase of the disease increases.

Of 271 observed recurrences of rheumatic fever, two thirds (67 per cent) were clinically associated with infections of the respiratory tract, while one third (29 per cent) were apparently spontaneous. The remaining twelve recurrences (4 per cent) were clinically associated with infections or traumas outside the respiratory tract. There is strong serologic evidence that recurrences are usually

Chart 5.—Clinical analysis of 271 recurrences of rheumatic fever in patients in the inactive phase of the disease at the time of the recurrence. Included in the total number of recurrences in the top panel, but not otherwise shown, are twelve recurrences clinically associated with preceding nonrespiratory episodes.

associated with hemolytic streptococcus infection recurrences but may occur in subjects in the inactive phase of the disease in no relation to infection of the respiratory tract and in the absence of detectable sero-

logic evidence of an associated hemolytic streptococcus infection. A discussion of the hemolytic streptococcus as a possible etiologic factor in rheumatic fever involves features of the study which are beyond the scope of this report. However, from the data at hand it is apparent that infections of the upper respiratory tract and hemolytic streptococcus infections are important precipitating agents in rheumatic fever.

ABSTRACT OF DISCUSSION

DR. WILLIAM P. WHERRY, Omaha: The statements of the authors bear out common clinical observations, especially the statement that acute rheumatic fever can be a distal response to an upper respiratory infection. I question the premise assumed by Drs. Jones and Mote when they allocated the cases studied, using as a yardstick the frank, visual determination of the pathologic process in the pharynx and nose. The mucosal defense system of the nasal and paranasal sinus is their membrane and to cut off the dissemination of invading organisms, while on the other hand the sympathetic glands of the epipharynx and pharynx when overwhelmed tend to store up infection and pass it along into the blood stream. If this histopathogenic premise is correct, nasal and paranasal sinus involvement becomes a focus creating a possible distal hit only when the lymphatic glands are beyond the limits of tolerance. If the pathogenesis just suggested is correct, it is well to keep in mind the possibility that infectious reactions can originate in the remnants of lymphatic structure in the epipharynx and these resections are not infrequently the response from an overload of lymphatic stream coming from the nose. It is well to realize that the epipharynx has been the site of more poor surgery than any other region, and the result of poor adenoid surgery cannot but increase the potential field of response to upper respiratory infection. If statistics are to be accepted as worth while, the fundamental premise should be based on known pathologic change and sound methods of correction.

DR. WILLIAM D. STROUD, Philadelphia: The authors have confirmed in a scientific manner the clinical impression that most of us have obtained in the last few years, namely that head colds and streptococcic sore throats seem to play a definite part in the reactivation of latent rheumatic fever in children. About ten years ago we were first impressed with this fact at the Children's Heart Hospital in Philadelphia when one of the nurses developed a severe streptococcic sore throat. Our hospital is separated into two wards. She was working in only one ward and foolishly continued working all day and was then off duty a number of days. In two or three days, several of the children developed sore throats and some ten out of the thirty children exposed developed a fulminating reactivation of their rheumatic heart disease and had to be returned to the hospitals for acute diseases from which they had come. I should like to ask the authors whether they feel that in institutions such as the Good Samaritan Hospital in Boston, our Children's Heart Hospital in Philadelphia, possibly the Irvington House on the Hudson and the Ridge Farm here in St. Louis it is absolutely indicated that all in attendance should wear surgical face masks. Before the Climatological and Clinical Society, a few years ago, Dr. Douchet mentioned two cases that were interesting from this standpoint. Two children were in the ward recovering from rheumatic fever, their beds side by side. One of them had a positive Streptococcus haemolyticus throat culture and the other's throat culture was negative. The one with the negative throat culture developed a head cold and almost at once his throat became positive to Streptococcus haemolyticus. This suggests that head colds have something to do with lessening the resistance of individuals to bacterial disease. In treating these children with latent rheumatic fever we have a job similar to the treatment of active tuberculosis but in a reverse manner; that is, those who come in contact with patients whose sputum is positive for tuberculosis should be protected from infection, whereas we must protect children or young adults with inactive rheumatic fever from those around them who are carrying latent or active infections, especially in the nose and throat.

DR. T. DUCKETT JONES, Boston: In answer to Dr. Stroud's question I would say that face masks would be of help only in making one conscious of the purpose for which they are worn and not because they would necessarily prevent the spread of infections. However, I think it is an important feature in the care of patients with such a disease as rheumatic fever to see that, by collecting them in aggregates, such as chronic disease hospitals and convalescent homes, we are not increasing their exposure to respiratory infections rather than decreasing them. Isolation of these patients at the very first evidence of respiratory infection and in separate rooms, as opposed to cubicles, is I believe almost the only way of handling such a situation. Protection from exposure to respiratory infection in nurses, doctors, attendants and visitors should be insisted on. In some places throats are being cultured prior to allowing visitors to see patients. This is a serious matter because respiratory infection at once spreads through the wards in institutions where there are a large number of rheumatic patients and often results in an epidemic of rheumatic fever. We have had one or two such small epidemics, and there are several in the literature. Concerning Dr. Wherry's remarks, I am not quite clear concerning what he meant as to obvious infections and nonpathologic conditions plus sound methods of correction, but I would say that I did not wish to raise the question of tonsillectomy, because so far as we have seen there is relatively little difference between hemolytic streptococcus pharyngitis and hemolytic streptococcus tonsillitis. The demonstration of an actual antistreptolysin response is the most direct evidence of a recent streptococcic infection. This specificity of the determination of antistreptolysin has been questioned by one or two observers, but in general it has been accepted. We feel that its use in the present studies makes our statistics quite reliable.

SURVIVAL FOLLOWING REMOVAL OF MALIGNANT RENAL NEOPLASMS

JAMES T. PRIESTLEY, M.D:
ROCHESTER, MINN.

In any review of late results following nephrectomy for malignant tumors of the kidney, the particular type of neoplasm which has been removed should be considered. Although adenocarcinoma (also termed "hypernephroma") is by far the most common malignant growth which occurs in the kidney, epithelioma of the renal pelvis, sarcoma and Wilms' tumor are not infrequently encountered. The clinical course, age of the patient, pathologic characteristics, indications for treatment and prognosis are some of the pertinent features which vary widely depending on the histologic nature of the growth. With the primary purpose of determining late results, the records of 642 cases in which operations were performed for malignant tumors of the kidney at the Mayo Clinic in the years 1910 to 1936 inclusive have been reviewed. Nephrectomy was performed in 568 cases and in the remaining seventy-four cases an exploratory operation revealed an inoperable lesion. The operations were performed by a number of surgeons. Of these 642 patients, 502 had an adenocarcinoma, sixty-two had an epithelioma, thirty-two had a sarcoma, thirty-seven had Wilms' tumor and the remaining nine either had some rare form of growth or the exact histologic diagnosis was not ascertained. Previous reports that have been made on the survival rate following the removal of malignant renal neoplasms

From the Division of Surgery, the Mayo Clinic.
Read before the Section on Urology at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 18, 1939.
The statistics in this paper were compiled with the aid of Dr. Joseph Berkson, chief of the Division of Biometry and Medical Statistics, the Mayo Clinic.

included some of the cases presented in this study.¹ These reports were based on smaller groups of cases and were prepared in a somewhat different manner. Symptoms, diagnosis, details of surgical and roentgenologic treatment, and observations on the pathologic changes will not be considered at this time, as the present study is concerned primarily with ultimate results following operation.

Chart 1.—Relative incidence of males and females in 642 cases of malignant renal growths.

INCIDENCE ACCORDING TO SEX AND AGE

As shown in chart 1, adenocarcinomas and epitheliomas of the kidney are definitely more common among men than they are among women, whereas sarcomas and Wilms' tumors occur with approximately equal frequency in the two sexes. As is well known, Wilms' tumors constitute the common renal malignant neoplasm of childhood, whereas adenocarcinoma and epithelioma have their greatest incidence in the sixth decade of life and are comparable in this regard to the common malignant lesions which occur elsewhere in the body. Sarcoma of the kidney occurs most frequently in the fourth, fifth and sixth decades of life (chart 2).

SURGICAL ASPECTS

Unfortunately, in a certain number of cases of malignant tumor of the kidney the lesion is inoperable when the diagnosis is first established. Data pertaining to operability in the present series of cases would probably not be representative of the general incidence of operability as patients frequently come for examination purely for corroboration of a diagnosis that indicated a hopeless prognosis. Nephrectomy was performed in 88.5 per cent of the 642 cases and an exploratory operation was carried out in the remaining cases. It is thus seen that a renal neoplasm is seldom inoperable purely because of its size and local extension. Renal tumors comparable in size to a large grapefruit usually can be quite satisfactorily removed. When a tumor is extremely large, preoperative roentgen therapy may occasionally reduce its size or cause other changes in the growth which facilitate nephrectomy.

Commonly it is the presence of distant metastatic involvement which is demonstrable objectively when

the patient is first examined that renders the lesion inoperable. In fact, a metastatic lesion occasionally may be responsible for the first recognizable symptom of an adenocarcinoma of the kidney. Under these circumstances any direct surgical attack on the primary lesion obviously is contraindicated. I have no doubt that small metastatic lesions, which are actually present when nephrectomy is performed but which are not detectable at this time by any method of clinical investigation, are responsible for some of the deaths which occur within the first year following operation. In other cases tumor thrombosis in the renal vein and the dislodgment of thrombi into the vena cava at the time of operation may account for some of the early deaths following operation. Care should always be taken to avoid such an occurrence. Complete removal of the growth without rupture is of course always desirable.

Simple nephrectomy, performed through a posterolumbar incision, was the operation performed in practically all cases except when dealing with an epithelioma. In a few cases in which the growth was exceptionally large an anterior, transperitoneal approach was utilized. When dealing with an epithelioma of the renal pelvis, complete nephro-ureterectomy is the procedure of choice and is now carried out in all cases unless there is some definite contraindication. This is done either as a single operation or occasionally as a two stage procedure, the kidney being removed first and subsequently the remaining portion of the ureter and a small segment of the bladder surrounding the ureterovesical orifice. In a number of the earlier cases in which operation was performed before it was realized that ureterectomy as well as nephrectomy was the procedure of choice for epithelioma, the late results have been far less satisfactory than those which have been obtained since nephro-ureterectomy became the routine procedure. Thus only 26.7 per cent of the patients who were traced were living five or more years following simple nephrectomy for epithelioma of the renal pelvis, whereas 60 per cent were living the same length of time following nephro-ureterectomy for the same condition.

Chart 2.—Age distribution of patients in percentage according to type of malignant neoplasms of the kidney in 642 cases.

The immediate operative mortality (all hospital deaths) following operation for tumors of the kidney gradually has been reduced. The mortality in the entire group of 568 cases in which nephrectomy was performed in the years 1910 to 1936 inclusive was 7.5 per cent. For the ten years prior to 1936 the mortality was 5.3 per cent (263 cases), for the five years prior to 1936 the mortality was 3.1 per cent (127 cases) and for the three years prior to 1936 the mortality was 1.2 per cent (eighty-five cases).

GENERAL SURVIVAL RATE

For the purpose of determining the survival rate, only those patients who were operated on prior to 1934 (482 in all) are considered. It should be stated that the survival rate was calculated by first selecting the patients who had been operated on a sufficient number of years prior to the investigation (three or five or ten years, according to the survival rate calculated) and by considering only those who had been traced for that number of years. Those patients who could not be traced for the required period were not considered in calculating the survival rate, as it was impossible to determine whether they had or had not survived for the duration of the survival period being considered. This method is considered by Berkson² to give a more accurate estimate of the true survival rate than the method of calculation commonly employed formerly, in which all patients who could not be traced were considered to be dead, an obviously inaccurate assumption. As shown in table 1, however, practically all (99 per cent) of the patients were traced.

Chart 3.—Survival rates following nephrectomy according to type of neoplasm.

There are various factors which influence the survival rate³ following the removal of a malignant renal neoplasm. One of the most important factors which affect ultimate results is the type of tumor that was removed, as shown in table 1 and chart 3. It may be seen that of all patients who were traced following nephrectomy for adenocarcinoma 47.7 per cent survived three or more years, 38.4 per cent survived five years or more and 27.3 per cent lived ten years or longer. It is apparent that the greatest mortality occurred within the first three years following operation and that a patient who survived three years after the operation had a better chance of living an additional seven years or more than he did of surviving the first three years after his operation. It is equally obvious that an increasing number of patients who succumb more than three years following operation die, according to mortality figures for the general population of comparable age groups, of causes entirely unrelated to the renal tumor, since the death rate from all causes increases rapidly with age after 50 years.

Late results following operation for epithelioma of the renal pelvis are roughly comparable to those for adenocarcinoma, except for the ten year period. Of

the patients who were traced, 44.7 per cent lived three or more years, 35.0 per cent lived five years or more but only 10.5 per cent survived for ten years or longer. In contrast, the survival rates following extirpation of renal sarcoma or Wilms' tumor are definitely lower. Only 17.4 per cent of patients operated on for sarcoma

Chart 4.—Survival rates, according to grade of malignancy, in cases of renal adenocarcinoma.

survived three or more years after operation and only 5.9 per cent lived ten years or longer. Following nephrectomy for Wilms' tumor 23.5 per cent survived three or more years and 9.1 per cent lived ten years or longer after operation. It is hoped that results in the treatment of Wilms' tumor may be more satisfactory in the future than they have been in the past, now that roentgen therapy is employed in a routine way pre-operatively as well as postoperatively in the treatment of this tumor.

INFLUENCE OF GRADE OF MALIGNANCY ON SURVIVAL RATE

The grade of adenocarcinoma removed, according to Broders' classification, is of definite prognostic significance in a large series of cases, as illustrated in table 2 and chart 4. As has been shown to be true repeatedly

Chart 5.—Survival rates according to weight of renal adenocarcinoma removed.

in regard to malignant lesions elsewhere in the body, the survival rate following removal of high grade adenocarcinomas of the kidney is distinctly lower than that which follows removal of adenocarcinomas of low grade. Thus 73.3 per cent of patients who had a grade 1 adenocarcinoma survived for three or more years after operation in contrast to only 22.2 per cent of those who had a grade 4 tumor. The contrast was even more marked ten or more years after operation when these figures decreased to 47.6 per cent and 3.2 per cent respectively. While the grade of a lesion may not be

2. Berkson, Joseph: Personal communication to the author.

3. Investigation of the survival rate was conducted as of Jan. 1, 1937. Thus the group used in calculating the three year survival rate comprises patients treated three or more years prior to the time of inquiry, namely 1933 or earlier; the five year group comprises those treated in 1931 or earlier; the ten year group comprises those treated in 1926 or earlier. All survival rates were calculated according to the method shown in table 1, which is the standard system for such investigations conducted at the Mayo Clinic. Table 1 is presented in unabridged form.

sufficient evidence in itself on which to base an accurate prognosis in a single case, the general percentage of survivals according to the grading of tumors is obviously important in estimating the average life expectancy following operation for adenocarcinoma of the kidney. There are too few cases of the other types of tumors to permit accurate calculation of ultimate results according to the histologic grade of the tumor.

INFLUENCE OF WEIGHT OF TUMOR ON
SURVIVAL RATE

The size of the tumor has a definite influence on the survival rate, as shown in chart 5. Thus 46.5 per cent of patients who had tumors that weighed 500 Gm. or less survived five or more years after operation, whereas only 24.6 per cent of those who had tumors that weighed 1,000 Gm. or more remained alive for a similar length of time. Ten or more years after operation these figures were 39.1 per cent and 13.0 per cent respectively. These data suggest the importance of local extent of the growth in prognosis. Extension of the tumor into the renal capsule, perirenal tissues, lymph nodes surrounding the renal pedicle, the peritoneum and other

has been suggested that preoperative irradiation is of value in the treatment of adenocarcinoma of the kidney.⁵ This is not employed as a routine at the clinic but is used only in those cases in which the growth, in the absence of metastasis, is of such enormous proportions that from a local point of view it is virtually inoperable. Under these circumstances preliminary irradiation may be worth a trial. There is an insufficient number of cases other than adenocarcinoma to attempt any statistical evaluation of the effectiveness of roentgen therapy.

Current opinion is most uniform regarding roentgen therapy in the treatment of Wilms' tumor. It is almost unanimously agreed that both preoperative and postoperative irradiation are desirable when dealing with this type of tumor.⁶ Nephrectomy should be performed usually from four to six weeks after the preoperative irradiation is started, at the time when there is maximal reduction in size of the growth and before secondary enlargement occurs. Postoperative irradiation should be given over the entire abdomen and thorax as well as applied to the renal region from which the tumor was removed.

TABLE 1.—Survival Rates Following Nephrectomy for Malignant Renal Neoplasms*

Type of Renal Neoplasm	Patients Operated on		Lived 3 or More Years After Operation		Patients Operated on		Lived 5 or More Years After Operation		Patients Operated on		Lived 10 or More Years After Operation	
			Patients	% of Traced Patients			Patients	% of Traced Patients			Patients	% of Traced Patients
Adenocarcinoma.....	395	392	187	47.7	362	357	137	38.4	257	253	69	27.3
Epithelioma.....	47	47	21	44.7	40	40	14	35.0	19	19	2	10.5

* Investigation as of Jan. 1, 1937. The three year group comprises the patients treated three or more years prior to the time of inquiry, that is, 1933 or earlier; the five year group comprises those treated in 1931 or earlier; the ten year group comprises those treated in 1926 or earlier.
† Only simple nephrectomy was performed in some of the earlier cases.

adjacent structures very definitely decreases the chance of ultimate cure. Likewise the occurrence of tumor thrombosis within the renal vein, which is not an uncommon finding, renders the prognosis less favorable. Occasionally, tumor thrombosis can be pushed back in the renal vein toward the kidney and thus removed or at times it may be extracted from the renal vein or vena cava.⁴

ROENTGEN THERAPY

The exact indications for, and the value of, roentgen therapy in the management of renal tumors in general remain undetermined. Analysis of the cases of adenocarcinoma in which roentgen therapy was not used and those cases in which "inadequate" or "adequate" roentgen therapy was used failed to disclose a higher survival rate for those who received irradiation. This is equally true whether all cases are considered in a single group or whether they are tabulated according to the grade of tumor that was present. It is realized that these results may be inconclusive because it is possible that for the most part roentgen therapy was used in cases in which the prognosis was unfavorable. If this is true, the cases in which irradiation was used are not representative of the entire group. A review of the data according to the weight of the tumor did not show any consistent difference in the survival rates, whether or not roentgen therapy was administered. It

MISCELLANEOUS OBSERVATIONS

It was observed that the survival rate of patients who had a relatively normal concentration of hemoglobin was definitely higher than that of those who had some degree of anemia. Thus 40 per cent of the patients in whom the concentration of hemoglobin was 80 per cent or higher survived ten or more years after operation, whereas only 20 per cent of the patients in whom the concentration of hemoglobin was 60 per cent or lower lived an equal period of time. The exact significance of such an observation is difficult to determine. It seems possible that those patients who had lower values for hemoglobin may well have had more extensive growths with a large amount of hematuria and possibly some unrecognized metastasis. Likewise the patients with low leukocyte counts (6,500 or less) had a higher survival rate than did those with higher counts. An explanation of this observation will not be ventured.

SUMMARY

This study is based on an analysis of 642 cases in which operation was performed for malignant tumors of the kidney in the years 1910 to 1936 inclusive. Of these patients 502 had an adenocarcinoma, sixty-two had an epithelioma, thirty-two had a sarcoma, thirty-seven had a Wilms tumor and nine had miscellaneous growths.

Adenocarcinoma and epithelioma of the kidney are more common among men than they are among women. Nephrectomy was performed in 88.5 per cent of 642 cases and the lesion was considered inoperable in the remaining 11.5 per cent. The survival rates were ascertained for 482 patients who were operated on prior to 1934. The general survival rates in cases of adenocarcinoma, for three or more, five or more, and ten or more years after operation, were 47.7 per cent, 38.4 per cent and 27.3 per cent respectively. Similarly, the survival rates for similar periods in cases of epithelioma were 44.7 per cent, 35.0 per cent and 10.5 per cent respectively. In cases of Wilms' tumor the survival rates for similar periods were 23.5 per cent, 20.0 per cent and 9.1 per cent respectively and in cases of sarcoma the respective survival rates were 17.4 per cent, 13.0 per cent and 5.9 per cent. In general, the survival rates in cases of adenocarcinoma vary with the grade of the tumor; the lower the grade of malig-

nancy, the higher is the survival rate. The survival rates following nephrectomy vary with the weight of the tumor removed; the lower the weight of the tumor, the higher is the survival rate.

ABSTRACT OF DISCUSSION

DR. WILLIAM P. HERBST, Washington, D. C.: I should like to comment on one factor that Dr. Priestley mentioned in the technic of nephrectomy and ureterectomy, in which he emphasized the importance of removing the intracystic portion of the ureter and which according to his statistics results in a very definite improvement in the late results. I think that is a rather important factor, and naturally the question occurs to some as to whether the increased mortality incident to the extensiveness of this particular type of surgical procedure is completely compensated for by the improvement in the end results. I think that is something which must in the end resolve itself and must be followed out according to the judgment of the individual who is taking care of the case.

Sex Differences with Respect to Psychoses.—With the exception of the manic-depressive psychosis and involutional melancholia, the first-admission rate for all of the principal psychoses is higher for men than for women. The admission rate for men for involutional melancholia is less than half that for women, while for manic-depressive insanity the male rate is but four-fifths as high as the rate for women. For all psychoses combined, the male rate is 34 per cent higher. The two outstanding male diseases are the alcoholic psychoses and general paresis. For the former disease the male first-admission rate is about seven times as great as the corresponding female rate and for the latter 3.5 times as great. With respect to the remaining psychoses the male rate is from 8 to 86 per cent higher.—Landis, Carney, and Page, James D.: *Modern Society and Mental Disease*, New York, Farrar & Rinehart, Inc., 1938.

THE EFFECT OF CERTAIN ANESTHETICS ON THE BLOOD

PAUL W. SEARLES, M.D.

BUFFALO

In the literature are numerous reports concerning the concentration and coagulation of the blood during ether anesthesia. Recently the concentration of blood in the course of anesthesia with sodium amytal has received considerable attention, but the results of these investigations have not been uniform. The observations for the most part have been made on clinical patients subjected not only to the anesthetic but to some operative procedure as well. It has been my purpose in this research to investigate the uncomplicated effect of ether anesthesia and sodium amytal anesthesia on the number of erythrocytes of the blood and to establish the uncomplicated effect of ether anesthesia on the coagulation time of the blood plasma.

The majority of the investigations concerning the effect of ether anesthesia on the number of circulating erythrocytes have shown an increase. Hamburger and Ewing¹ found in the dog an increase of 15 per cent in the hemoglobin content and an increase of 10 per cent in the number of erythrocytes following ether anesthesia. Barbour and Bourne² showed that fasted dogs allowed water up until the time of the experiment obtained increases in blood solids during ether anesthesia. This increase ranged from 2.1 to 3.4 per cent. Bourne³ found in a second series of dogs, with an elevation of the environmental temperature to 33 C. (91.4 F.) accompanied by the administration of fluids beforehand, that there resulted negligible changes in body temperature and blood solids in dogs anesthetized with ether. Also morphine administered prior to the ether anesthesia protected the animal against the concentration of blood.

Drabkin and Edwards⁴ found no change in the blood solids with sodium amytal. However, Bourne, Bruger and Dreyer,⁵ conducting experiments on both dogs and man, found a definite decrease in the blood solids with sodium amytal anesthesia, the maximum occurring after one hour. They observed a marked enlargement of the spleen under phenobarbital and suggested that the same might be true with sodium amytal. Adolph and Gerbasi⁶ concluded that the blood solids of dogs were greatly decreased under sodium amytal. They splenectomized one dog and found that no change occurred in the blood solids under sodium amytal anesthesia.

There exists a wide variation of results concerning the effect of ether anesthesia on the experimental animal. Two of the most accurate observations were made

by Mendenhall⁷ and Zopff.⁸ Mendenhall, experimenting on decerebrated cats and using whole blood, found an average decrease of 15 per cent in the blood clotting time and explained it on the basis of a stimulation of the adrenals. A closer analysis of his results shows an actual increase in the time required for clot formation and in others no change at all, which, however, was offset by a general tendency toward a shorter coagulation time. Zopff, working with dogs and in a much smaller series, confirmed these results. In addition to observing a decrease in the coagulation time Zopff found an increase in the platelet count during and after ether anesthesia.

EXPERIMENTAL PROCEDURE

Our experiments were confined to healthy normal dogs. Two blood samples were withdrawn as controls prior to the administration of the anesthetic, care being taken to insure a minimum of excitement during the process. Blood was withdrawn from the cubital, saphenous or jugular vein, a different vein being selected for each puncture. The anesthetic was administered immediately after the control samples of blood had been taken. Ether anesthesia was induced in an ether chamber and maintained by the auto-inhalation method. Light surgical anesthesia was maintained for the first

were collected at the end of the first and second half hour periods. In addition, blood samples were collected after anesthesia. In the case of ether, this was done one hour after the removal of ether, while with sodium amytal an arbitrary period of four hours after induction of anesthesia was chosen.

Chart 1.—Increases and decreases of cell volume, hemoglobin content and erythrocyte count with ether and with sodium amytal anesthesia, respectively.

thirty minutes and deep surgical anesthesia for the next thirty minutes. When sodium amytal was used, 50 mg. for each kilogram of body weight was injected intravenously. During anesthesia, duplicate blood samples

Chart 2.—Curves of cell volume, hemoglobin content and erythrocyte count before and after ether anesthesia in intact and in splenectomized dogs.

The hemoglobin values were determined by the Sheard-Sanford photoelectric method.⁹ Hematocrit studies were made by the use of standard tubes. For the hematocrit reading the blood was drawn into heparin and the tubes centrifuged for thirty minutes at approximately 1,500 revolutions a minute. The erythrocyte counts were made by the use of standard hemocytometers. The clotting time was determined with the blood plasma coagulability test, the end point being detected by the use of the coagulometer devised by Baldes and Nygaard.¹⁰ This technic requires the use of a photoelectric cell. Blood platelets were done by Nygaard's¹¹ modification of Thomsen's¹² direct method of counting platelets in oxalated blood.

RESULTS

Each of three dogs was anesthetized with ether on three different occasions to determine the changes in the coagulation time of the blood plasma and the blood platelet count. In this series of nine experiments the coagulation time was not significantly changed. It might, however, be stated more specifically that in two

experiments there were no changes in the coagulation time of the blood plasma with ether anesthesia, in one experiment there was a slight increase, while in the remaining experiments there were slight decreases. When the average figures for the nine experiments were considered, there was an average decrease of 3 per cent in the coagulation time at the end of a half hour, of 9 per cent at the end of an hour and of 7.5 per cent at the end of four hours of anesthesia. The average normal control value was eighty-six seconds. In eight of nine experiments the number of platelets was increased. The average for the entire series was an increase of 78,000 blood platelets per cubic millimeter of blood.

Ether anesthesia caused a definite increase in the number of erythrocytes of the peripheral blood in a series of nine animals. After one hour of ether anesthesia there was an increase of 18 per cent in the cell

After removal of the spleen the values for cell volume, hemoglobin and the number of erythrocytes were increased, but the increases were about half as great as those obtained in the unsplenectomized animal under ether anesthesia. The average increase after splenectomy was only 7.6 per cent in cell volume, 12 per cent in hemoglobin content and 11 per cent in the erythrocyte count (chart 2). Splenectomy abolished completely the reduction of the erythrocytes of the blood which occurred in the normal intact animals under sodium amytal anesthesia. An average of the results obtained from splenectomized animals after one hour of sodium amytal anesthesia showed no change in cell volume, a 6 per cent rise in hemoglobin and a 4 per cent rise in the erythrocyte count (chart 3).

Similar observations were made on three animals in which the spleen had been previously denervated; changes in the erythrocyte values of the blood of these animals were comparable to those in the normal intact animal.

COMMENT

Changes in the coagulation time of the blood plasma with ether anesthesia were small, the average decrease being 9 per cent. It is doubtful whether so small a change is of significance. This decrease in coagulation time was less than the decrease of 15.2 per cent obtained by Mendenhall⁷ using whole blood. The increase in the platelet count with ether anesthesia parallels the increase in the red blood cell count, the hemoglobin content and the cell volume. It is improbable that the increase in the blood platelets under ether anesthesia played any part in the slight decrease obtained in the coagulation time.

The majority of the more recent reports on changes in the blood with ether anesthesia have shown an increase in the cellular elements. The principal concern in this study has been to determine some of the factors regulating this increase in the constituents of the blood of dogs under ether anesthesia. Contraction of the spleen has been frequently observed in animals under ether anesthesia. It has been shown that removal of the spleen reduced by one half the increase in the erythrocyte count which occurred with ether anesthesia in the normal intact animal. Therefore it appears probable that the greater blood concentration obtained in the normal intact animal is due to a considerable extent to the spleen contracting and thus forcing out its accumulated cells into the general circulation. The increase in erythrocytes obtained with ether anesthesia in the splenectomized group of animals may be due to loss of fluid and a consequent concentration of erythrocytes.

By means of experiments with sodium amytal and ether anesthesia on animals with denervated spleens, we have shown that alterations in the number of erythrocytes were not dependent on a nervous mechanism. Hargis and Mann¹³ showed that the splenic reflex was abolished on denervation of the spleen. In our studies ether anesthesia given to three animals in which the spleen had been denervated caused the same increases in blood concentrations as those obtained by us in the normal intact animals.

The possibility that epinephrine might be responsible for the contraction of the spleen was not investigated. Emerson¹⁴ states that unequivocal evidence of the sup-

Chart 3.—Curves of cell volume, hemoglobin content and erythrocyte count before and after sodium amytal anesthesia in intact and in splenectomized dogs.

volume, 18 per cent in the hemoglobin content and 15.5 per cent in the erythrocyte count. In contrast to ether anesthesia, sodium amytal anesthesia produced a decrease in the cell volume of 21 per cent, in the hemoglobin content of 22 per cent and in the erythrocyte count of 19.7 per cent (chart 1).

The marked change in the cellular constituents of the blood with ether anesthesia and sodium amytal anesthesia occasioned a search for the mechanism involved. Accordingly a group of experiments was carried out in an attempt to explain the part played by the spleen in altering the number of erythrocytes of the blood under ether anesthesia and under sodium amytal anesthesia. Three animals on which determinations of the number of erythrocytes had been made previously were splenectomized. Two weeks after the splenectomy studies were made on these animals with ether anesthesia and four weeks later with sodium amytal anesthesia. In addition, two dogs whose spleen had been removed eight years and five years previously were anesthetized first with ether and then with sodium amytal.

13. Hargis, E. H., and Mann, F. C.: A Plethysmographic Study of the Changes in the Volume of the Spleen in the Intact Animal, *Am. J. Physiol.* 75: 180-200 (Dec.) 1925.

posed action of ether on the adrenals is as yet lacking but firmly believes that ether anesthesia does stimulate the output of epinephrine.

The 20 per cent reduction in the number of erythrocytes of the peripheral blood obtained in the normal intact animal with sodium amytal anesthesia failed to occur in the same animals after splenectomy. We have observed that the spleen increases enormously in size under sodium amytal anesthesia. It therefore seems probable that the spleen in dilating removes the corpuscular elements from the general circulation and by this mechanism causes a reduction in the circulating erythrocytes.

SUMMARY

In a study of the effects of ether anesthesia and sodium amytal anesthesia on the circulating erythrocytes and the coagulability of the blood plasma, the coagulation time of the blood plasma under ether anesthesia was slightly decreased. There was an increase in the blood platelet count with ether anesthesia. Ether anesthesia caused an increase in the cell volume, the hemoglobin content and the erythrocyte count. Removal of the spleen reduced by one half the increase in the cellular constituents which occurred in the normal intact animal under ether anesthesia. Sodium amytal anesthesia caused a decrease in the cell volume, the hemoglobin content and the erythrocyte count. Splenectomy abolished completely the decrease in the cell volume which occurred in the normal intact animal under sodium amytal anesthesia.

Buffalo General Hospital.

ABSTRACT OF DISCUSSION

DR. CHARLES J. BETLACH, Chicago: This study and others show that ether anesthesia has little significant effect on the clotting mechanism. It has been known for some time that ether produces a concentration of the red cells. Dr. Searles's work shows that this change is related to changes in the spleen and changes in the plasma volume. That splenectomy reduces this concentration to only one half indicates that loss of plasma volume probably accounts for the other 50 per cent concentration. McAlister in 1937 showed that etherization reduces the plasma volume 11.9 per cent in dogs. The contraction of the spleen during ether anesthesia removes one of the protective physiologic mechanisms which go into action when hemorrhage occurs. These two factors, contraction of the spleen and loss of plasma volume, seem to set the stage for the onset of shock. Morphine and preoperative intravenous fluids protect the animal against this concentration of blood. In a study on eight patients undergoing cyclopropane anesthesia, Taylor and Waters in 1935 found no changes in the red cell count. Sodium amytal, on the other hand, causes an enlargement of the spleen and dilution of the blood. This dilution is prevented by splenectomy. Adolph and Gerbasi however have shown by measurement of dry residue and specific gravity that there is a true transudation of fluid into the blood stream during sodium amytal anesthesia. These changes would lead one to the conclusion that shock could be delayed by sodium amytal as compared to ether. This has been worked out by Seely, Essex and Mann, who showed that shock in dogs, caused by manipulation of the intestine, developed in one third the time under ether anesthesia as compared to sodium amytal anesthesia. This brings up the interesting possibility of the intravenous use of barbiturates to alleviate pain and to prevent the onset of shock in the transportation of wounded soldiers during wartime. In 1875 Claude Bernard showed that a leukocytosis occurred during anesthesia. Ether and cyclopropane produce the most marked changes, the count being doubled or tripled depending on the duration of anesthesia. The maximum is reached in from four to eight hours and it requires from three to five days for the count to return to normal. Spinal and local anesthesia cause one half the rise that ether does and the response to nitrous oxide is interme-

diated between that produced by ether and by local anesthesia. The polymorphonuclear cells increase both relatively and absolutely. The absolute number of lymphocytes remains the same.

DR. PAUL W. SEARLES, Buffalo: I think the knowledge that ether anesthesia causes a concentration of the blood can be of value when anesthesia is to be considered in a debilitated patient. With ether anesthesia one must also consider the administration of fluids beforehand to protect the patient against possible concentration of the blood. The normal spleen acts in an emergency as a reserve blood transfusion. Ether anesthesia deprives the patient of this reserve blood by causing the spleen to contract and expel its contents into the general circulation immediately on induction. A normal patient can withstand a loss of this blood reserve in the spleen, but the same is not true with a markedly debilitated patient. The addition of fluids preoperatively and in some cases the choice of an anesthetic such as an intravenous barbiturate which will not contract the spleen but actually causes the spleen to dilate must be considered. Intravenous barbiturates will give a fairly satisfactory anesthesia, although the degree of relaxation obtained is not as good as with ether anesthesia. However, some degree of relaxation can well afford to be sacrificed when the condition of the patient does not warrant giving an ether anesthesia. I don't think that the coagulation of the blood is altered with ether anesthesia. Ether anesthesia is listed as one of the possible precursors of pulmonary embolism. I think factors other than ether anesthesia are the probable causative agents of postoperative embolism.

THE RATIONAL TREATMENT OF SINUSITIS IN CHILDREN

JOHN J. SHEA, M.D.

MEMPHIS, TENN.

The rational treatment of sinusitis depends on a sane appreciation of the newer anatomic and physiologic facts, the result of clinical and experimental studies.¹ The diagnosis must distinguish between conditions the result of infection and of allergic manifestations.

The treatment of sinusitis in children differs from that in adults in that the rhinologist hopes to terminate their infections or correct their allergic disturbances, thus obtaining a permanent cure. The value of sulfanilamide therapy is a disputed question, with opinions of wide variance being given by different authorities.²

There are two schools of thought regarding the ability of the sinuses to enter into the autoimmunization of a patient against infections of his environment. The conservative idea is that the sinuses play no part, but the modern that they are capable of sharing with the members of Waldeyer's ring a selective immunization against the infections that invade the upper respiratory tract.

The patient with sinus disease can be helped by local treatment, medicinal therapy, diet, climate, immunization, electrotherapy and surgical intervention.

LOCAL TREATMENT

In the infant the treatment should be directed against the stuffy nasal membrane and the enlarged adenoid. Solutions of salts of ephedrine and epinephrine are

Read before the joint meeting of the Section on Laryngology, Otolaryngology and Rhinology and the Section on Pediatrics at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 19, 1939.

safe in the hands of the physician but should rarely be prescribed. The commercial nasal drop may owe its popularity to a craving it creates. Such a drop to become popular generally contains some derivatives capable of shrinking the nasal membranes.

It is foolish for a man to prescribe a nasal drop without inspecting the nasal membrane. Hypotonic salt solutions may be used to shrink the nasal membrane by their osmotic power. The solution is placed in the nose in saturated cotton packs placed in the middle meatus or is instilled into the nose while the patient is in one of the positions advocated by Parkinson.³ In either instance the solution must remain in position sufficiently long to shrink the turbinates and open the ostiums of the sinuses. The exposure to infra-red radiation increases its efficiency.

A second pack is selected according to the stage of the inflammation: 1. During the stage of acute rhinitis a 1 per cent oily solution of phenol will lessen the engorgement. 2. If the discharge is purulent one of the protein silver solutions (10 per cent mild protein silver dissolved in a solution made by mixing equal parts of glycerin and water) will serve as a solvent and assist in the ready removal of the discharge. 3. Ichthammol solutions are useful to relieve the dry type by increasing the secretion of mucus.

When either of the last two solutions has been instilled into the nose, removal is demanded at the end of the treatment. In the infant and the young child this is best accomplished by direct suction after the fashion of Haskin⁴ with a soft rubber catheter or a small glass pipet. To Coffin⁵ belongs the credit of initiating the use of intermittent suction and pressure for the drainage of the sinuses. This is best accomplished in the younger child by placing him in the prone position. If the discharge in the older child is more postnasal than anterior, displacement in the prone position is more productive than a similar irrigation in the upright position. The anatomic explanation of this is that the ostiums of the posterior ethmoid cells face backward into the superior nasal meatus.

The allergic patient does not tolerate the protein silver packs, but a weak solution of a zinc salt (1:1,000 zinc sulfate) is beneficial as an irrigating solution. Likewise, the allergic nasal membrane may resist shrinking by the simple hypotonic salt solution and require the addition of one of the ephedrine derivatives. The instillation into the eye of one drop of a preparation made up of one-half ounce (15 cc.) of a 0.25 per cent solution of zinc sulfate and .1 drachm (4 cc.) of a 1:1,000 solution of epinephrine will shrink the inferior turbinate after descending through the lacrimal passage into the nose. The use of a benzedrine inhaler or a spray containing a solution of epinephrine hydrochloride diluted to 1:60,000 will shrink the membrane of the upper passage of the nose. To maintain the shrinkage of any of these solutions it is best to administer one-eighth grain (0.008 Gm.) of ephedrine hydrochloride by mouth with a corresponding dose of a

barbital (one-eighth grain of soluble phenobarbital). This combination may be prescribed as a follow-up treatment until the next office visit. The patient is made more comfortable by ending the treatment with the instillation of a bland oily spray to protect the membrane. To facilitate the distribution of the oily nasal drop into the nasopharynx, the child is instructed to protrude the tongue forward. This act lowers the palate and uvula, thus releasing the constrictor action of the pharynx. In the older child the instillation of the oil up through the nasopharynx into the nose delivers the solution under the turbinate bones and bathes tissues not touched when the drops are instilled anteriorly.

MEDICINAL THERAPY

During the acute stage the administration of a prescribed mixture may be of value and a prescription may be based on one of the following substances:

(a) Codeine or morphine sulfate may be used for the relief of pain or as a sedation to arrest a cough. The use of Dover's powders, once very popular, is losing favor because of the frequency of nausea.

(b) Monobromated camphor is an antispasmodic. Quinine is preferred by some physicians for this role.

(c) Caffeine in the form of a citrate relieves the headache and as a stimulant neutralizes the depressant action of the salicylates.

(d) Salicylates form the principal part of the prescription. Today acetylsalicylic acid is popular and inexpensive.

(e) Iodine has long been one of the best alternatives of materia medica. Five minims (0.3 cc.) of tincture of iodine U. S. P. in 2 ounces (60 cc.) of water acts locally and replaces a gargle. In the stomach it acts as a functional stimulant and after its absorption increases the discharge of the sinuses and nasal membranes.

The only combination of drugs which I have found to lessen the size of hypertrophied lymphoid tissue is composed of calcium compounds⁶ and thyroid and parathyroid. Judiciously used, this combination may be administered over a period of several years without unduly disturbing the normal endocrine balance. Nervousness, restlessness and daily elevation of temperature are contraindications to the continuation of the use of this prescription. To avoid such disturbances, the combination may be given for five days and spaced five days by the administration of the vitamins.

(f) Accessory treatment is a most important therapeutic measure in the treatment of sinusitis. During the acute stage, drugs which increase the appetite and assist the digestion are preferred. After the child has improved, his general health should be maintained by the administration of cod liver oil or concentrates of vitamins A and D. When the latter are given, they are more efficient if administered when the stomach is empty.

(g) Sulfanilamide and its modifications are of distinct value in the control of sinusitis the result of infection by streptococci. One of the disadvantages of their administration is the drying of the secretions within the sinuses. They should not be given in mixtures or used except in the acute stage and under special precautions.

WHEN TO IRRIGATE A SINUS

A sinus may be irrigated during the acute stage to relieve pain and occasionally to lower fever. Ventilation should be maintained by local procedures during the acute stage and irrigation of the sinuses reserved for the clean-up. It is a good practice never to irrigate when the fever is rising, but many a protracted cold could be terminated by the irrigation of the proper sinus. Dilation of the natural ostium of the antrum is important, as its closure occurs at the onset of the sinusitis.

Frontal Sinus.—The choice of cannula, malleable or fixed, depends on the surgeon. A roentgenogram is necessary as a road map of direction. A small amount of fluid is used and must be displaced by pressure to avoid a painful vacuum after the treatment.

Maxillary Sinus.—The closure of the natural ostium is one of nature's few blunders, and the improvement of sinusitis demands its dilation. Irrigation of an antrum should be done after the fashion which the surgeon can employ with the least amount of pain and with the most thorough result. A tray for this purpose may be likened to a golf bag, containing instruments capable of negotiating many angles. I prefer the natural ostium, for by utilizing it one is reestablishing the normal route of drainage.

Sphenoid Sinus.—A good rhinologist irrigates the empyemas of the sphenoid sinus the same as those of the other sinuses, following the customary indications and precautions. Occasionally I use a straight needle after locating the ostium with a probe.

External Drainage.—In cases of severe involvement in which internal drainage has failed or intracranial or orbital rupture is feared, external drainage of the frontal sinus is necessary. This can be accomplished easily with local anesthesia, and when one considers that the blockage may be an inch in length, one can appreciate the impossibility of internal drainage. The incision for the Lynch radical operation on the frontal sinus is made and entrance into the sinus accomplished with a small burr. The frontal sinus is emptied of its contents and a small catheter drain inserted through the window thus made.

DIET

A well balanced diet rich in vitamins and minerals is better than any artificial combination. An excess of carbohydrates increases the quantity of purulent discharge, so it is now customary to eliminate sweets during an acute attack of sinusitis. The allergic patient should be tested, as certain foods will be his most active trigger. The cutaneous reactions are but a saga of the past, and only by the use of a trial diet can one determine the present culprit in the menu.

CLIMATE

There is no ideal climate in our country in which sinusitis does not exist. A change of climate is beneficial, and persons who live in the mountains may do better at the seashore or on the plains, while the inhabitants of the latter are improved by a sojourn in higher altitudes. In the summer months in regions of active ultraviolet radiation, resistant infections clear up: During the winter the climate best suited for the patient with sinus disease is warm, with moderate changes and a minimum amount of rainfall.

The more chronic a condition is, the longer must be the climatic change. It is foolish to expect a radical improvement in a patient with chronic sinus disease by a month's sojourn. The patient should be kept

away at least a full winter and spring, for a disappointing recurrence may follow the early return of a patient to his native city before the break of the bad weather at home. A patient who has improved one year should be advised to return for a second year, as the colds of childhood may interrupt the normal development of the sinuses, leaving an arrested condition throughout life.

IMMUNIZATION

If the sinuses enter into the autoimmunization, a child possessing a normal group of sinuses obtains no help from cold serums but a child with diseased or persistent infantile sinuses may need the help of a good vaccine. A modified autogenous vaccine made from the child's secretions obtained during the first cold of the winter may be employed. The vaccine is administered throughout the severe weather, one or two doses a week being given to maintain immunity, as this is very expendable. Vaccines for oral use are in the experimental stage.⁷ Intranasal vaccine appears to hasten the coagulation of the discharge and clinically is of merit.

ELECTROTHERAPY

The exposure of the face during infra-red irradiation elevates the local temperature and serves as a sedative.⁸ At bedtime it is a good bedtime story. The elevation of temperature is accompanied by a change of blood in the vessels of the membrane, and the heat may be registered in distant parts.

Ultraviolet irradiation is beneficial to the child with sinus disease and may be substituted for a change of climate. The administration of calcium compounds and the vitamins in combination with this irradiation increases the efficiency of each.

Short wave therapy is more potent than infra-red irradiation and is tolerated by the membranes with less after-effects.⁹

Roentgen therapy assists in the treatment of sinus disease, locally by its action on the blood vessels by relieving congestion and by its blockage of the lymphatic drainage.¹⁰ The application of the ray to the lymphoid tissue of the nasopharynx, pharynx and neck decreases this tissue and indirectly assists the sinuses.¹¹

SURGICAL INTERVENTION

There are children who cannot be sent south with whom local treatment, diet and immunization have failed and the sinuses have become a focus of infection. These children will not submit to frequent irrigations of their antrums because of fright and pain. Something must be done, and the best results are obtained by giving the child a general anesthetic, dilating the natural ostium and draining the sinuses through an artificial window under the inferior turbinate bone.

This procedure is not intended for the treatment of acute sinusitis except when the general condition of the child demands immediate relief from an infection within the antrum.¹²

CONCLUSIONS

1. The rational treatment of sinusitis depends on a sane appreciation of the newer anatomic and physiologic facts, the result of clinical and experimental studies.

2. The treatment of sinusitis in children differs from that in adults in that the rhinologist hopes to terminate their infections or correct their allergic disturbances, thus obtaining a permanent cure.

1018 Madison Avenue.

ABSTRACT OF DISCUSSION

DR. LEE WALLACE DEAN JR., St. Louis: If the nasal mucosa is well shrunken with ephedrine or neosynephrin the swelling may return in two hours, so that in order to keep the nasal mucosa aerated and the ostiums of the sinuses patent this shrinking must be repeated several times daily. I have never observed addiction to vasoconstrictors in young children, although it is only too common in adults. I do see, however, a vasomotor rhinitis in children resulting from the prolonged administration of ephedrine. It has been my habit to warn mothers against commercial nose drops and make my ephedrine prescriptions nonrefillable in order to combat the misuse of such drugs. Lipoid pneumonia has attracted much attention of late, especially that of Walsh and Cannon, as far as our specialty is concerned. Children with congenital heart disease and other debilitating conditions are particularly prone to suffer from lipoid retention in the lungs.

DR. HARRIS HOSEN, Port Arthur, Texas: In the use of nonspecific therapy in acute diseases we can draw no real scientific conclusions, for acute disease varies with the virulence of the infecting organism. I am dubious though tolerant of the therapy of acute sinusitis. But in the use of nonspecific therapy in chronic sinusitis we can feel assured that if a cure results the treatment is responsible. I do not believe that children with chronic sinusitis should be sent to another climate, for results attained are palliative only. With proper treatment the majority of children can be cured of this condition. I have reference to a bacteriologic cure which is permanent and not to a clinical cure, which is often a creature of the imagination. My technic of treatment consists of open drainage plus the use of autogenous vaccine. Antral puncture with irrigation is done weekly until no visible pus is evident. Pus is rarely present after six washings. Autogenous vaccine is given every three to five days for fifteen doses. Enough vaccine is given to cause a local reaction regardless of the dose required. A naso-antral puncture can be performed under local anesthesia in the average child over 6 years of age. Evipal anesthesia is ideal for children of 5 years or over who will not tolerate the local procedure. For younger children a light anesthetic of ether is reliable. While the patient is under an anesthetic, the use of an antral rasp to enlarge the antral opening is advisable, but it must be remembered that such an opening will close in two or three weeks. At the end of a full course of treatment the antrums are again irrigated and the washings examined. If the washings are negative macroscopically, they are centrifuged and the sediment is examined microscopically. If no bacteria are found, the case is considered bacteriologically cured. If bacteria are present in moderate abundance, the patient is given a three months rest. After this rest the antral washings are again examined. If pus is present a second course of treatment is given. If no pus is present but bacteria still exist, a second course of vaccine alone is given. A third course is rarely necessary.

DR. CLIFFORD SWEET, Oakland, Calif.: I disagreed with Dr. Shea in San Francisco last year, and I have to disagree with him this morning. I don't believe that ephedrine is habit forming. My only difficulty in using a properly made ephedrine

solution in children's noses for the relief of congestion is that I can't get the mother to keep it up long enough. She stops before the child is well. We should not put either hypotonic or hypertonic solutions into the nose. The introduction of any hypotonic solution into the nose robs the cells of their normal salt content and one of the best ways of making cells irritable is to rob them of their normal salt content. Any solution that is introduced into the nose not only should be isotonic with the body but it will be less irritating if it also has the same pH . There is a very simple way of making a solution that is of the same pH as the body and that is to make it with filtered boiled tap water rather than with distilled water, because the human body and the tap water of the community are always of a constant pH . One per cent ephedrine added to an isotonic solution does not change the esotonicity of that solution because the ephedrine is a very large organic molecule which does not dissociate into ions. Therefore the solution remains isotonic in spite of the addition of the ephedrine. I have worked with Dr. Sidney Parkinson and I have used this solution for the release of heavy nasal secretions for a period now of eight or nine years, with no untoward results and with no children that I can think of being submitted to operation for relief of their sinusitis. As for packing the noses of small children, I should like to borrow a phrase from Dr. Joseph Brennemann, who said "No child should have his throat swabbed until he reaches the age of consent." I think that no child should have his nose packed until he reaches the age of consent.

DR. T. E. WALSH, Chicago: Dr. Shea's paper shocked me. First he called attention to the new ideas of the physiology and anatomy of the nose and then he went on to advocate treatments that have been shown by all the workers in the physiology of the nose to be absolutely contraindicated. He uses epinephrine to shrink the nasal tissues. Dr. Proetz has shown that epinephrine immediately stops ciliary action and that cilia will not recover except after a considerable period of time. He advocated the use of hypotonic salt solution, and there again the cilia are immediately stopped when they are immersed in hypotonic solutions. I would suggest that all treatment of acute upper respiratory infections should be directed along rational lines with a knowledge of the physiology behind it. Nature has given us a first class line of defense against infection in the mucous coating of the nose and the active cilia; provided we keep the mucous coat intact and the cilia active there is little chance for chronic infection or for infection to get down deep in the subepithelial tissues and give the chronic sinusitis and the distressing symptoms that one sees in older children. If we keep our hands out of these children's noses, treat them with the mildest possible shrinkage solutions and be very careful not to allow those solutions to get down into the chest, the children will get well of their own accord without our help.

DR. GEORGE PINESS, Los Angeles: I disagree with Dr. Shea's statement that cutaneous tests are a thing of the past and that elimination diets were a solution to food problems. I wish to impress the section with the important fact that children after they are a few weeks old have been exposed to these environmental factors that we as adults are exposed to and that foods per se are rarely the only factors that produce respiratory symptoms in the allergic child. My experience with a large series of children proved that only one in a hundred was sensitive to foods and foods alone, and that over 70 per cent of this group had multiple sensitivity. I wish to add emphasis to what Dr. Walsh has said about the use of solutions in the nose, particularly oily solutions. I advocate the use of the synthetic ephedrine-like substances in isotonic solution instead of ephedrine, which has a tendency to produce insomnia, extreme nervousness and other constitutional reactions in children. I know of no synthetic preparation that causes the constitutional reactions mentioned. Elimination diets have a limited value, since it is most difficult to pick out the offending food through them. Experience teaches that usually the mother and child are the best judges of the food or foods that cause symptoms and are much more apt to discover them than the physician who attempts to guess what may or may not be the offending food. Conservatism should be employed in the treatment and care of the allergic child. My experience is that sinusitis in childhood is a rather rare thing, particularly the chronic type.

12. Shea, J. J.: Fifteen Years' Experience with Drainage Tubes After Antrostomy in Children, Arch. Otolaryng. 24: 14-18 (July) 1936.

DR. JOHN J. SHEA, Memphis, Tenn.: In answer to Dr. Hosen, I prefer an autogenous vaccine to which I add a stock vaccine. The stock vaccine is made up of the intercurrent infections in one's own environment at the time. I take it from acutely infected throats, mastoids and sinuses. I feel that vaccine therapy is very commendable. Whether it is a question of immunization or desensitization, it must be continued over the whole winter that the child is under treatment. I use a very mild hypotonic salt solution. There have been a lot of nasal drops used, and there are still a lot of nasal drops used, but there have been very few of these lipid pneumonias reported. We as clinicians are in a peculiar position on this. Either our pathologists have fallen down on the job or not given us good reports. I think we have got to take that exhibit and their conclusions with a little skepticism until other men confirm their observations, because there are many oily nasal drops that are being used. One sees in the treatment of bronchiectasis large amounts of iodized oil injected into chests that are already pathologic. I have seen for many years in otolaryngologic practice the installation of the preparation guaiacol given into the larynx, but there have been very few autopsies to confirm their reports, and so I think that we need more proof on that. I don't disagree with Dr. Piness one bit. I merely said that your skin test is a saga of the past, that it is a history of that child's previous reaction to infections, and that one has to be guided by it with the use of an eliminating diet.

THE TREATMENT OF IMPERFORATE HYMEN WITH HEMATOCOLPOS

A REVIEW OF 113 CASES IN THE LITERATURE AND
A REPORT OF FIVE ADDITIONAL CASES

PENDLETON TOMPKINS, M.D.

PHILADELPHIA

The syndrome known as imperforate hymen with hematocolpos has been recognized for centuries and yet is seldom diagnosed by the physician who first sees the patient. More than 300 years ago Ambroise Paré described a case in which, because of amenorrhea, pain and abdominal swelling, the condition was diagnosed as pregnancy. Today the syndrome is more often mistaken for appendicitis or tuberculous peritonitis and the patient inadvisedly subjected to laparotomy. Even when the condition is properly diagnosed, the results of treatment are often unsatisfactory. In the University Hospital one death followed treatment. This fatality led to a review of the subject in the hope that another such occurrence might be prevented.

FREQUENCY

Hematocolpos resulting from an imperforate hymen is neither a new nor a particularly rare condition, 113 cases having been reported in the literature.¹ In the Gynecologic Service of the Hospital of the University of Pennsylvania there have been five cases in twelve years (1926 to 1938). Gordon² found eleven cases recorded at Bellevue Hospital in twenty years. Palmer³ observed four cases in thirty-two years of practice, and Hammond⁴ observed seven cases.

Read before the Philadelphia Pediatric Society, Jan. 10, 1939.

Because of lack of space this article is abbreviated here by the omission of a bibliographic table. The complete article appears in the author's reprints.

From the Gynecologic Hospital Institute of Gynecologic Research and the Department of Gynecology of the Hospital of the University of Pennsylvania.

1. These are listed in the table, which appears only in the author's reprints.

2. Gordon, O. A., in Curtis, A. H.: *Obstetrics and Gynecology*, Philadelphia, W. B. Saunders Company, 1933, vol. 3, p. 635.

3. Palmer, H. E.: *J. Florida M. A.* 12:99-101 (Oct.) 1925.

4. Hammond, F. C.: *Atlantic M. J.* 29:690-691 (July) 1926.

PATHOLOGIC PROCESS

Hematocolpos results from complete vaginal obstruction to menstrual flow. Such obstruction during adolescence is usually caused by an imperforate hymen, but occasionally it is due to congenital retrohymenal atresia⁵ or to agglutination of the labia as a result of chronic infection and uncleanness. Hematocolpos has also been reported in cases of double vagina when one outlet is occluded. In any case, blockage of menstrual flow produces first dilatation of the vagina, later dilatation of the cervix and uterus, and finally dilatation of one or both tubes. It has been suggested that this condition leads to endometriosis. I have not discovered a report of such a case, and from reading descriptions of the observations at laparotomy have gained the impression that hematosalpinx is seldom accompanied by spilling of blood into the peritoneal cavity. The fimbriated extremities of the tubes are usually closed, possibly because of "sterile salpingitis." It has also been suggested that chronic distention produces irreparable damage to the generative organs and sterility. I do not know whether chronic distention in such cases actually produces permanent structural damage, because the organs are seldom available to the pathologist for study. One such study was made in the clinic of this hospital (case 4). There was little microscopic evidence of damage except that attributable to secondary infection. That long-standing distention does not necessarily produce sterility is shown by Searle's⁶ patient, who complained of amenorrhea at the age of 17, had the hymen excised at the age of 32, with release of much old blood, and at 36 was delivered of a healthy child. Oppenheimer⁷ and Rollins⁷ have also reported pregnancies subsequent to treatment. I have followed three of our patients for two, five and seven years. None reported menstrual disorders. One patient was married for six months and did not become pregnant.

CHARACTER OF THE RETAINED BLOOD

The dammed-up blood is thick, dark and "molasses-like" or "tarry." Chemical studies⁸ are of less interest than bacteriologic studies. As would be expected from the clinical picture, the blood is sterile.⁹ If blood has been retained for a long time, as in the older patients, it is usually more viscid than if it has recently accumulated. McIlroy⁹ observed three sisters with imperforate hymens. The youngest was operated on before the appearance of symptoms, and it was noted that the released blood was not as thick as that evacuated from the older sisters. McIlroy and Ward appear to be the only authors who have reported the diagnosis and treatment of hematocolpos before the onset of symptoms. Their report suggests that imperforate hymen may be a familial variation.

SYMPTOMS

There are three principal symptoms of hematocolpos with imperforate hymen. Amenorrhea, strangely enough, is seldom offered as a complaint. The patient's mother generally assumes that her daughter is simply

"slow to grow up" and does not associate the abdominal pain with failure of the menses to appear. Pain is the second symptom and is usually poorly localized in the lower abdomen. Typically it is dull and intermittent rather than severe and constant. These qualities, together with the history of previous attacks "about a month apart," often suggest recurrent appendicitis and sometimes lead to unnecessary laparotomy. Severe pain is almost always due to overdistention of the bladder. The third symptom and, contrary to several statements, a very common one, is inability to void or difficulty in voiding. An imperforate hymen should always be suspected when an adolescent girl who has not menstruated complains of disturbance referable to the bladder. Snodgrass¹⁰ has stated that in cases of hematocolpos inability to void is due to pressure on the urethra. The only pressure on the urethra is due to intravaginal fluid, and so, if this idea is to be accepted, it must be assumed that the intravaginal pressure exceeds the intra-urethral pressure at the moment of micturition. Since these pressures have not been measured and compared, there is little to support Snodgrass's explanation of the urinary symptoms. They may well be due to kinking of the urethra or to distortion of the base of the bladder as the anterior vaginal wall elongates with the accumulation of blood. Another possibility is that vaginal distention interferes with the reflexes necessary to normal micturition.

In addition to the three principal symptoms, amenorrhea, pelvic pain and disturbances referable to the bladder, there may be abdominal enlargement, a protruding mass at the vulva or pain on sitting.

DIAGNOSIS

An imperforate hymen may be found at any age. It is most commonly discovered between the ages of 11 and 18 when obstruction to menstruation begins to produce symptoms. The diagnosis can be made at once by inspection if the physician thinks of the possibility of imperforate hymen. The hymen will be found completely covering the vaginal orifice; frequently it is bulging and, if thin, is bluish. If there is hematocolpos, rectal examination will reveal a fluctuant mass in the vagina which may displace the uterus. Usually it is impossible to palpate the tubes because of the vaginal and uterine masses. Distention of the bladder is so common that the patient should always be catheterized before the size of the hematocolpos is estimated. The quantity of retained blood (from 50 to 1,000 cc.) will be astonishing unless one remembers that the capacity of the vagina is great and that the symptoms are due almost entirely to distention. Laboratory work helps little in the diagnosis. Anemia is infrequent. A leukocyte count as high as 20,000 per cubic millimeter is usually found and has occasionally contributed to an erroneous diagnosis of appendicitis. If an imperforate hymen is found in conjunction with a fluctuant vaginal mass, it is unnecessary to aspirate the fluid or to make x-ray studies¹¹ after injection of a radiopaque medium into the vagina in order to confirm the diagnosis. It is wiser to proceed directly to treatment.

TREATMENT

Several problems in treatment require consideration. Shall the hymen simply be incised, shall a cruciate

incision be made or is it best to excise the entire membrane? Although satisfactory results may follow simple incision, complete excision is the procedure of choice. A wide opening will permit rapid drainage of fluid and lessen the likelihood of infection. Whatever surgical intervention is undertaken must be accomplished with the most scrupulous regard for asepsis. Postoperative care is unusually important; suggestions will be presented later.

Whether to allow the dammed-up blood to evacuate itself spontaneously, as it will in the course of perhaps twelve hours after excision of the hymen, or whether to remove it by vaginal lavage on the operating table is another question. Since the vaginal contents are sterile prior to operation it would seem safe to employ a douche of sterile, nonirritating fluid to wash out the accumulated blood. This plan has been followed with good results elsewhere, but I have had no experience with it.

How to deal with palpably distended tubes is a more difficult problem. Before reviewing the literature I had supposed that chronic distention of the uterus and tubes would lead to sterility. I should have agreed with Belson,¹² who said "If there is evidence of a tubal tumor, a laparotomy should be performed and a radical operation done removing all pathological organs," and I should have felt that removal of damaged tubes was no great loss to the patient. However, in view of reports of pregnancy subsequent to long-standing hematocolpos, the question is more perplexing. Should one open the abdomen and remove the tubes or should one risk the chance of ascending infection of the engorged tubes? The one fatality at the University Hospital was the result of infection in a tube, which, because of torsion, had failed to empty itself into the uterus after excision of the hymen. There are but few case reports on which to base an opinion. Probably the safe policy would be to perform a laparotomy whenever tubal distention is palpable and to incise and drain the tubes or to remove them, whichever seems wiser at the operating table.

COMPLICATIONS

The chief complication of any of these procedures is ascending infection leading to pelvic inflammatory disease, peritonitis or death. Old blood is an excellent culture medium, and once infection enters the vagina the dilated cervix, uterus and tubes offer no obstacle to its ascent. This is the most cogent argument for removal of the blood by lavage. In the 113 cases reviewed there were six deaths and nine severe pelvic infections. Possibly this incidence of severe complications exaggerates the dangers of the treatment, for many of them occurred before the era of aseptic surgical technic. Yet fatalities still occur. I know from personal experience that infection and death may occur several weeks after the patient leaves the hospital. Lack of follow-up data in the literature makes it impossible to estimate the frequency of such complications today.

Postoperative hemorrhage sufficient to require secondary suturing is rather common. This complication probably is not due entirely to faulty surgical technic. It is quite possible that the retained blood, which is uncoagulated and which, after its release, drains for some hours over the hymenal incision, has an anticoagulant property which favors postoperative hemorrhage.

12. Belson, M. O.: *Am. J. Surg.* 36:221-225 (April) 1937.

SUGGESTED PLAN OF TREATMENT

1. Meticulous preoperative preparation of the vulva and perineum.
2. Complete excision of the hymen, not simple incision.
3. No vaginal examination at the time of operation.
4. After evacuation of the hematocolpos on the operating table a careful rectal examination to determine whether there is distention of the tubes. If there is evidence of hematosalpinx, laparotomy should be performed and the tubes should be incised and drained or, if necessary, removed.
5. A postoperative vulvar dressing of gauze soaked in mercury bichloride solution.
6. High Fowler position to promote drainage.
7. Enough morphine to produce constipation for at least four days after operation.
8. Careful cleansing of the perineum after every evacuation.
9. At least one week of rest in bed (in the Fowler position) after the temperature is normal.
10. No tub bathing or swimming and no douching until two menstrual periods have occurred.
11. No vaginal examination until two menstrual periods have occurred. This examination should be made with sterile precautions.

REPORT OF CASES

CASE 1.—*Complete recovery, patient followed for seven years, married.*

F. W. H., a white girl aged 16, admitted Jan. 15, 1931, had as her chief complaint pain in the lower part of the abdomen at monthly intervals for one year and pain recurring oftener than once a month for the past three months. Imperforate hymen was diagnosed by the referring doctor. General physical examination gave negative results. Pelvic examination disclosed an imperforate hymen. Rectal examination revealed a large cystic mass filling the vagina and pushing the uterus up to the level of the umbilicus. Laboratory examination showed 3,900,000 red cells, 84 per cent hemoglobin and 6,700 white cells. Operation, January 17, consisted of complete excision of the hymen. The convalescence was afebrile and uneventful. The patient was discharged on the eleventh day after operation. Follow-up by questionnaire in October 1938 disclosed that the periods occurred regularly every twenty-eight days, lasting six or seven days. The patient required three napkins a day and had slight dysmenorrhea the first two days. She had been married for six months and had not become pregnant.

CASE 2.—*Severe pelvic infection following operation, eventual recovery, patient observed for five years, not married.*

B. S., a Jewish girl aged 14, admitted Aug. 18, 1933, had as her chief complaints absence of menstrual flow, a lump in the abdomen and pain in the abdomen and back. The breasts had begun to enlarge three years previously. About a year before admission cramping pain in the lower part of the abdomen developed at monthly intervals, continuing for a week at a time. An abdominal mass was noted four weeks before admission, and three days before admission the patient was unable to urinate. She was catheterized by her physician, who referred her to the hospital for treatment. General physical examination disclosed nothing abnormal except a cystic pelvic mass reaching to the umbilicus. Pelvic examination revealed a bulging, fluctuant, purplish, imperforate hymen. Laboratory examination showed 4,300,000 red cells, 93 per cent hemoglobin and 12,000 white cells. Operation, August 19, consisted of excision of the hymen. The uterus lay at the level of the umbilicus; the cervix could not be felt by vaginal palpation, even after a large quantity of old blood had been released. The convalescence was satisfactory for the first week; then the temperature rose abruptly and for ten days ranged between 100 and 105 F. It subsided gradually and was normal for twelve days before the patient was discharged. The fever, accompanied by leuko-

cytosis (31,000 white cells) and anemia (58 per cent hemoglobin) was attributed to infection in the left adnexal region, where a tender mass was palpable. Follow-up by questionnaire in September 1938 disclosed that the periods were regular every twenty-eight or thirty days, lasting four or five days. Four napkins a day were used. There was no dysmenorrhea. The patient had not married.

CASE 3.—*Complete recovery, no follow-up.*

J. H., a white girl aged 13, admitted July 21, 1934, had as her chief complaint pain in the abdomen for eighteen hours. She had been in good health until she was awakened by sharp pain in the right lower quadrant. The referring physician suspected appendicitis. No menstrual flow had appeared. General physical examination gave negative results. Pelvic examination revealed a fluctuant, blue, bulging, imperforate hymen. Laboratory examination disclosed 5,200,000 red cells, 92 per cent hemoglobin and 9,000 white cells. Operation, July 24, consisted of complete excision of the hymen with drainage of 500 cc. of old blood. The patient was put in the Fowler position and a vulvar dressing of gauze saturated in mercury bichloride solution applied. The convalescence was uneventful and afebrile. The patient was discharged on the eighth day after operation. No follow-up report was obtainable.

CASE 4.—*Discharge from hospital in good condition, generalized peritonitis and death one month later, infected ruptured hematosalpinx revealed at autopsy.*

M. C., a Negro girl aged 14, admitted April 24, 1936, had as her chief complaint low backache for one year, enlargement of the abdomen and urinary frequency, urgency and nycturia for several months. The menstrual flow had not appeared. General physical examination disclosed nothing abnormal except a pelvic mass rising halfway to the umbilicus. Pelvic examination revealed an imperforate hymen. Rectal examination demonstrated a pelvic mass reaching halfway to the umbilicus. Laboratory examination revealed 4,000,000 red cells, 75 per cent hemoglobin and 16,600 white cells. Operation, April 27, consisted of complete excision of the hymen with release of a considerable quantity of old blood. Vaginal examination then revealed a dilated cervix admitting two fingers. The uterus was enlarged to the size of a 2½ months pregnancy. Convalescence was afebrile and uneventful. The patient was discharged on the eighth day after operation. Follow-up pelvic examination May 20 (twenty-three days after operation) disclosed "satisfactory progress."

The patient was readmitted to the hospital May 28 in a moribund condition. It was stated that she had been in good health until May 25, when abdominal pain developed. She was kept in bed with fever, nausea and general malaise. Three days later, when she became irrational, she was brought to the hospital. The temperature was 101 F. (axillary), and the pulse and blood pressure were not perceptible. Laboratory examination revealed 4,200,000 red cells, 77 per cent hemoglobin and 10,600 white cells. The clinical diagnosis was fulminating generalized peritonitis. The patient died three hours after entering the hospital. Autopsy confirmed the diagnosis. The uterus was well contracted and no larger than normal. The right tube was retort shaped, 17 cm. in length and 3.5 cm. in diameter. The fimbriated extremity was closed, and the tube, which was filled with old blood, had undergone complete torsion, which probably accounted for the failure of the blood to drain through the uterus and vagina after excision of the hymen. There was a small perforation in the tubal ampulla. The left tube was retort shaped, 12 cm. in length and closed at the fimbriated extremity. Microscopic examination revealed no abnormality in the vagina, a thickened but normal endometrium, thrombosis and engorgement of the vessels with edema and areas of necrosis in the right tube and an essentially normal left tube. The pathologist's diagnosis was acute diffuse peritonitis presumably resulting from infection and rupture of an undrained right hematosalpinx.

CASE 5.—*Complete recovery, patient followed two years.*

J. A. F., a white girl aged 12½ years, admitted Oct. 5, 1936, had as her chief complaint mass and tenderness in the lower part of the abdomen and the left side. The symptoms had appeared two months before. The pain was not severe; there

was no nausea or vomiting. Sixteen days before the pain had recurred, accompanied by frequency of urination, slight nausea and some pain in the upper part of the abdomen. General physical examination gave negative results. Pelvic examination revealed an imperforate hymen. Rectal examination demonstrated a mass filling the pelvis. Laboratory examination disclosed 4,900,000 red cells, 85 per cent hemoglobin and 12,000 white cells. Operation, October 8, consisted of complete excision of the hymen. One quart of chocolate-colored old blood was evacuated. The uterus was twice normal size, and the adnexa were not palpable. A drainage tube was inserted in the vagina. Convalescence was uneventful. The patient was discharged on the tenth day after operation. Follow-up by questionnaire in November 1938 revealed that the periods were regular every twenty-eight days, lasting four or five days. Three napkins a day were used. There was occasional mild dysmenorrhea.

SUMMARY

Imperforate hymen with hematocolpos is not rare, although only 113 case reports have been found in the literature. The chief symptoms are pain in the lower part of the abdomen and urinary disturbance in a patient whose menses have not yet appeared. Responsibility for diagnosis rests with the physician who first sees the patient, usually the general practitioner, general surgeon or pediatrician. In most instances diagnosis can be established by inspection alone. The danger of treatment is ascending infection leading to peritonitis. Because this danger is very real, treatment should be undertaken only in the hospital and preferably by a gynecologist.

807 Spruce Street.

ACUTE INFECTIOUS JAUNDICE

JOHN A. NORTON, M.D.

OCEANSIDE, CALIF.

Ordinarily acute catarrhal jaundice is not considered to be a communicable disease, although it is stated in Cecil's Textbook of Medicine¹ that it is occasionally seen in epidemic form. At present there is some confusion as to the terminology of the disease in question. Until research on this disease has made the etiologic agent definitely known, it would seem that the term "acute infectious jaundice" would be the most desirable. The disease is often confused with Weil's disease, which is also known as epidemic jaundice, infectious jaundice and leptospirosis, so that the term acute infectious jaundice would serve to distinguish this from true epidemic jaundice (leptospirosis) and would also serve to differentiate it from the sporadic cases of acute catarrhal jaundice due to inflammatory swelling around the opening of the common bile duct into the duodenum. It has been reported² that this disease was epidemic in Gallipoli during the World War. Blumer³ in 1923 gave a good summary of acute infectious jaundice in the United States. In 1936 Pickles³ reported 118 cases of epidemic catarrhal jaundice, in which thirty-nine cases showed a definite history of contact and in which there was an incubation period of from twenty-six to thirty-five days. It was his opinion that the method of spread was from person to person by droplet

infection. Jenikomshian and Dennis⁴ in 1938 reported thirty-seven cases. There were multiple cases occurring in eight families with an apparent incubation period of from ten to fifteen days. The most recently reported outbreak of this disease was given by Molner and Kasper⁵ in June 1938. They reported forty cases, of which thirty-seven fell into the age group of 5-15 years. They established a definite history of contact in 60 per cent of the cases.

THE OUTBREAK AT SILVER PEAK

In Silver Peak, Nev., there have recently been twenty-three cases of acute jaundice of an infectious nature. The first patient became ill on May 15, 1938, and the last patient on December 15. A summary of the cases is given in the accompanying table. In addition to the cases at Silver Peak there have been twenty-seven similar cases in the past few months in Nevada which occurred as follows: thirteen cases at Verdi, seven cases at Goodsprings, four cases at Manhattan and three cases at Tonopah. Only the cases at Silver Peak will be discussed in this paper, because it is the only one of these communities in which the population is not influenced by much travel and in which every case of jaundice occurring during this period was reported.

Silver Peak is a relatively isolated mining camp with a population of approximately 800 persons. The nearest railway depot is 55 miles away and during the first three months of this outbreak there was no physician within 55 miles. This village developed overnight with discovery of a body of rich silver and gold ore and the sanitation of the community is not satisfactory. Disposal of excreta is solely by means of poorly constructed, fly-infested privies. There is no central water supply for the community and many of the individual wells are in the lower section of the town, so that during rainy weather residents complain of tastes, odors and turbidity in the drinking water. The only milk supply is from an unclean dairy selling raw milk.

A clinical history was obtained from each of these patients and they are so similar that a summary of the average observations will suffice to represent the clinical picture. The average age of the patients was 14 years. The onset of early symptoms was usually rather sudden, with anorexia, nausea and sometimes vomiting. Within twenty-four hours the patients had diarrhea and abdominal pains, which were seldom severe. There was usually a temperature of around 100 F. Approximately one week after the onset of acute symptoms a definite icteric tint would develop in the scleras and within forty-eight hours the skin over the entire body would be definitely yellow. At approximately the same time the scleras would become tinted, the stools clay colored and the urine quite dark. In the average case there were no complications, but the duration of convalescence was prolonged for about four weeks. In eight cases there were no agglutinins against *Leptospira icterohaemorrhagiae* or *Leptospira canicola*.

Owing to the inaccessibility of this community in reference to medical and laboratory services, no clinical laboratory work was done during the acute stage of the patients' illnesses. The only laboratory work of note

1. A Textbook of Medicine, R. L. Cecil, editor, ed. 4, Philadelphia, W. B. Saunders Company, 1937, p. 806.

2. Blumer, George: Infectious Jaundice in the United States, J. A. M. A. 81: 353 (Aug. 4) 1923.

3. Pickles, W. N.: Epidemic Catarrhal Jaundice, with Special Reference to Its Epidemiology, Brit. J. Child. Dis. 32: 192 (July-Sept.) 1936.

4. Jenikomshian, H. A., and Dennis, E. W.: An Outbreak of Epidemic Jaundice at Hamet, Lebanese Republic, Tr. Roy. Soc. Trop. Med. & Hyg. 32: 189 (Aug.) 1938.

5. Molner, J. G., and Kasper, J. A.: An Outbreak of Jaundice in Detroit, J. A. M. A. 110: 2069 (June) 1938.

was performed by Dr. K. F. Meyer, director of the Hooper Foundation for Medical Research, San Francisco. He ran agglutination tests for *Leptospira* on each patient as indicated in the table. All these agglutination reactions were negative for *Leptospira*, so that Weil's disease (leptospirosis) can be rather definitely ruled out.

EPIDEMIOLOGY

In each case a careful inquiry was made relative to contact with another patient with this disease. As a result of this it was found that six patients gave a very definite history of close contact with a patient who

the onset of illness in one case to that in a second case with a definite history of direct contact varied from twenty-four to forty-five days, with an average of thirty-one days.

CONTROL MEASURES

Control measures were adopted October 8, and following the expiration of the expected incubation period after that date there were only four more cases. The control measures were approximately the same as for typhoid, since it was felt that this was a gastrointestinal infection probably spread by intimate contact and possibly through the water supply.

Summary of Histories of Cases in Epidemic of Acute Infectious Jaundice

Patient's Age, Case Initials Years	Onset of Illness	Onset of Icterus	Definite History of Contact	Milk Supply	Water Supply	Blood Agglutination Test for <i>Leptospira</i>	Early Symptoms
1 L. S. 17	5/ 8/38	5/13/38	Oak Creek, Ariz.	Not known	Private well	Anorexia, malaise and diarrhea
2 B. C. 13	6/20/38	6/26/38	None known	Silver Peak Dairy	Local well	Backache, abdominal pains and fever
3 A. Z. 11	6/22/38	6/25/38	Not definite	Silver Peak Dairy	Local well and bottled water	Negative 10/7/38	Anorexia, nausea, emesis and diarrhea
4 C. G. 6	7/10/38	7/16/38	Possibly case 1	Silver Peak Dairy	Local well	Anorexia, abdominal pains, back- ache, drowsiness and fever
5 A. P. 10	7/ 7/38	7/14/38	None known	Silver Peak Dairy	Negative 10/7/38	Asthenia and malaise
6 I. Z. 12	8/ 5/38	8/14/38	Case 3	Silver Peak Dairy	Local well and bottled water	Abdominal pains and fever
7 O. L. L. 5	8/ 7/38	8/12/38	None known	Local well	Pain in abdomen, swollen scrotum and anorexia
8 M. P. 13	8/12/38	8/19/38	None known	Silver Peak Dairy	Local well	Diarrhea and nausea
9 A. K. H. 30	8/12/38	8/19/38	None known	Silver Peak Dairy	Local well and bottled water	Negative 10/7/38	Backache, chills and fever
10 T. P. 13	Not known	8/16/38	Case 5	Silver Peak Dairy	Local well and bottled water	Negative 10/7/38	Acholic stools, malaise and icterus
11 W. H. Y. 30	8/18/38	8/25/38	None known	Silver Peak Dairy	Local well	Negative 10/7/38	Malaise, icterus and acholic stools
12 J. M. 23	9/ 6/38	9/12/38	Case 9	Silver Peak Dairy	Local well and soft drinks	Negative 9/17/38 and 10/4/38	Epigastric pain, backache, malaise, asthenia and emesis
13 R. L. 15	9/10/38	9/16/38	None known	Silver Peak Dairy	Local well	Abdominal pain, anorexia, eme- sis, backache, headache and fever
14 W. W. S. 33	9/20/38	10/ 3/38	Cases 9 and 11	Silver Peak Dairy	Local well and bottled water	Negative 10/4/38	Abdominal pain, headache, chills, fever, malaise and generalized aches
15 B. Y. 21	10/ 1/38	10/ 9/38	Case 11	None used	Local well and soft drinks	Negative 10/7/38	Abdominal pain, fever, diarrhea, malaise and generalized aches
16 F. L. 10	10/ 8/38	10/15/38	Case 13	Silver Peak Dairy	Local well	Fever, malaise and anorexia
17 F. E. B. 21	10/ 3/38	10/12/38	Not definite	Asthenia, anorexia, generalized aches and pains
18 J. F. E. 25	10/20/38	10/25/38	Case 14	Dark urine and icterus
19 B. P. 13	10/31/38	11/ 3/38	Case 16	Generalized aches, headache, emesis and dark urine
20 M. W. 31	11/ 9/38	11/16/38	None known	Local well	Abdominal pain, backache, malaise, generalized aches
21 N. B. O. 40	11/10/38	11/17/38	None known	Silver Peak Dairy	Bottled water	Malaise, headache, generalized aches, nausea, emesis and dysuria
22 L. K. 4	Not known	12/ 3/38	None known	Silver Peak Dairy	Artesian spring- bored
23 A. M. O. 19	12/15/38	12/22/38	Case 21	Silver Peak Dairy	Fountain drinks	Malaise, headache, generalized aches, nausea and emesis

had the disease earlier in the epidemic. In four additional cases there was a rather indefinite history of close contact with a preceding case. Patient 1 was a transient on her way to California to seek work in the agricultural industry. She gave a history of having spent the month preceding her residence in Silver Peak near Oak Creek, Ariz. She stated that while she was in Oak Creek there were several cases of jaundice (type undetermined) in the grammar school that she attended. A follow-up of this report by correspondence failed to show any known epidemic in Oak Creek. Case 2 had its onset forty-three days after the onset of case 1 and it seems quite probable that the entire twenty-three cases could be traced back to case 1. The time from

SUMMARY

The term "acute infectious jaundice" is proposed as the proper designation for those cases of jaundice usually designated as acute catarrhal jaundice, when there are multiple cases in a family or community. In the outbreak of acute infectious jaundice here reported it seems probable that the disease was transmitted by direct contact from person to person. The average incubation time of cases giving a definite history of contact was thirty-one days. The average age of these patients was 14 years. Weil's disease (leptospirosis) was rather definitely ruled out with negative agglutination tests done on eight patients.

111 North Freeman Street.

THE CONTRIBUTIONS OF PSYCHO- ANALYSIS TO THE STUDY OF PSYCHOSIS

IVES HENDRICK, M.D.

BOSTON

The interest of general psychiatry in the discoveries of psychoanalysis, and of psychoanalysis in the study of psychoses, have both greatly increased in recent years. In consequence, many of the contributions of psychoanalysis to the study of psychosis are widely known. But they are often looked at with various distortions of perspective. Thus a few enthusiasts consider them a complete explanation of psychotic phenomena. Others regard them as incidental and fail to recognize the almost revolutionary impetus they have given to all branches of modern psychopathology. Still more common has been the error of considering one aspect of the contributions of psychoanalysis to the study of psychosis as though it were the whole. The recognition of sexual symbols in schizophrenic thought, for example, are not infrequently regarded as Freud's chief contribution to this disease. Or the demonstration that the psychotic individual seeks pleasure in infantile ways is labeled a "fixation," and this is then considered an adequate explanation of etiology.

In this survey I shall try to avoid some of these errors. First of all, it is essential to recognize clearly which psychoanalytic contributions to psychosis are primarily applications of the study of psychoneurosis and dreams. Otherwise the student is too easily fascinated by the rediscovery of phenomena already demonstrated in the analysis of neuroses; he then overlooks the fact that his major and more difficult problem is to explain why psychosis is so different. The results of direct observation of psychosis will then be reviewed and finally I shall point out certain promising lines for further investigation which Freud has suggested but which neither he nor others have yet developed very much. He has been too busy.

APPLICATION OF ANALYSIS OF PSYCHONEUROSES AND DREAMS

The most universal fact established by the analysis of the psychoneuroses was the existence of unconscious mental life and the description of its characteristics and its effects on conscious thought, symptoms and behavior. Freud was then able to show how the biologic concept of adaptation was valid for all abnormal mental conditions. This one principle has revolutionized the most fundamental concepts of psychopathology. Today psychologically oriented psychiatry strives always to discern the purposefulness of a psychosis and to understand it as an adaptation of that individual to his emotional and his realistic needs, to his physical health and intelligence, and to the environmental stresses he endures. Eventually Freud translated the biologic principle of adaptation into the biopsychologic "pleasure-principle." This stated that the human organism is impelled by "drives" which are mentally experienced as emotions; that it seeks to maintain an emotional equilibrium and to reduce increments of affect-tension, and that events which satisfy this need for equilibrium are experienced psychologically as "pleasure." This principle, this "law" of the purposefulness of emotion, determines the

efficient, the "normal," reactions of the personality, but it also determines the less efficient or "abnormal" adjustments. Though Kraepelin achieved so much in the description and classification of psychotic symptoms, and though Pierre Janet had described the dissociation of hysterical personalities, neither of these great pioneers considered the purposefulness, the value to the personality, of the phenomena they studied. But Breuer and Freud¹ demonstrated this when they proved the relationship of hysterical symptoms to the repression of intolerable needs provoked by an adult trauma. By 1894 Freud² had already shown not only that obsessions and phobias as well as hysterical symptoms are adaptive phenomena but that a definitely psychotic symptom—hallucination—also serves a useful purpose. This was his first specific contribution to psychosis, and it was essentially a by-product of his study of hysteria.

But psychoanalysis soon led to more important things than the investigation of symptoms. It revised the notion that the psychoneuroses may be defined in terms of their symptoms, by showing that neuroses are actually the perpetuation of unsolved emotional problems of infancy and childhood. Can we today overlook that this is true of psychosis, and that delusions and hallucinations are not the psychosis itself but only two of its more obvious consequences?

A discussion of the details of the unconscious psychology of psychoneurosis and of the normal unconscious—the empirical and theoretical foundation of psychoanalysis—is beyond the scope of this paper, although almost every item has its daily applications in the clinical study of psychosis. But mention must at least be made of Freud's discovery of the relation of the pleasure seeking ("sexual") activities of the infant, his unrealistic fantasies, his pleasure in excretions, and his incestuous wishes to adult psychopathology. This knowledge not only has transilluminated the phenomena of sexual perversion and psychoneurosis, it has enabled the psychiatrist to see clearly the relation of much of the behavior and thinking of the deteriorated patient to normal trends of early periods of life. Many other facts discovered in the analysis of the psychoneuroses today constitute the basis of everyday comment in clinical psychiatry: the role of both past and immediate traumas in producing conflicts; the universal bisexual nature of man; the decisive role of homosexual desires even when they are unconscious; the many ways in which neurotic individuals avoid the conscious experience of unrecognized guilt, and the significance of primitive types of aggression in adult adjustments.

But Freud's greatest contribution to the specific psychology of psychosis is his study of a normal phenomenon: the psychology of dreams.³ Throughout the ages even the learned, as well as the psychologically intelligent, had spoken of the similarity of dreams and psychotic thought. Freud comments only incidentally, chiefly in footnotes, on this fact; but his intensive studies of dreams remain the most important contribution of all time to the psychology of psychosis. He showed that the irrational dream thoughts were not merely a hodgepodge of accidental excitations in a somnolent cortex but had definite meanings and were

as much an inevitable result of a given sequence of events as any product of the intellect. These conclusions followed from his detailed demonstration that the images in dreams are synthesized from fragments of waking perceptions and that these are selected for presentation in the dream by their associations with definite affect-arousing incidents in the life of the individual. He also showed that this selection is usually determined by the suitability of this or that fragment of a perception to represent one or more ideas in such a way that it will not be easily identified by the waking consciousness. He described the mechanisms which determine the syntheses and compromises of which a memory of a dream is the final result.

Every detail of this monumental work on the meaning of dreams, and their relationship to the experiences of the waking personality, has been shown to apply also to the previously incomprehensible content of psychotic thought. A schizophrenic individual is not only like the dreamer in being relatively oblivious to the real world as it is usually conceived but he accomplishes in his waking thought what the dreamer accomplishes in sleep. Both are survivals of a primitive type of thinking, characteristic of infancy and the animistic stage of culture, which antedates the mental differentiation of autistic and objective experience. This discovery established the basic principle of modern psychopathology, that logical thought is not so much a primary association of real relationships as a capacity, maturing relatively late in life, to correct autistic ideas. Psychotic thought appears strange to the normal mind not because it has no fundamental meaning, no relationship to the biologic and social needs of the individual, but because the observer insists on correcting psychotic ideas by the same logical processes he imposes, however imperfectly, on himself in his waking conscious experience.

This application of the investigation of dreams to schizophrenic thought was first worked out in detail by Carl Jung,⁴ at that time a colleague of Freud, who published his results in 1907. If one dissects out Jung's preoccupation with the theoretical relationship of the libido to his observations, one finds in this book the basis for the work of Storch⁵ and of all those others who have subsequently shown that delusions, hallucinations and motor speech, like dreams, are prelogical forms of thinking. The classic single contribution of psychoanalysis to this aspect of psychosis is Tausk's⁶ study showing how a schizophrenic patient's delusion that he was magically influenced by a machine was derived from his genital sensations. In this clinical specimen of prelogical thinking, Tausk discovered that the patient represented his genital organ by the idea of a machine, perceived it as though it were external to himself, and irrationally ascribed his sensations to this external and unreal source. Perhaps nothing could show more clearly the nature of schizophrenic thought than the comparison of Tausk's schizophrenic patient with a patient of mine—a nonpsychotic, hysterical woman. She disclosed during analysis a series of fantasies concerning her typewriter, which detail for detail duplicated the schizophrenic patient's ideas of an

influencing machine. The typewriter was like her genitals; she had peculiar sensations when she touched it; she was afraid when she must typewrite, angry at the machine and wished to destroy it. These fantasies were repressed but emotionally recalled in association to a dream. The schizophrenic patient's fantasy was not denied in waking life nor was it differentiated from objective experience, as was the hysterical woman's.

The investigation of the meaning of psychotic thought has today become a part of the routine of psychologically oriented psychiatric clinics. But several habits of professional thinking have often limited investigations in this field. Not a few psychiatrists have followed unwittingly in the footsteps of Wilhelm Stekel, whose fine analysis of the universal symbols which recur in dreams (such as snake for phallus, house for female genitals) led up a blind alley because he ignored those details of dreams derived from the individual experience of the dreamer. For symbols are elements of a dream which are shared by large numbers of the human race. Their translation into waking language does assist in understanding either dreams or psychotic thought. But, because they are "universal," they show more about racial history than the development of that individual. It is nevertheless true that universal symbols are much more frequent and important components of the total mental life of most psychotic people than of others. This quantitative difference was shown quite dramatically by a man whose thought processes and personal relations were predominantly of a schizophrenic type. After many months of analysis a fundamental change occurred in both his way of thinking and his human relationships; at this very time the character of his dreams altered. Previously the universal symbols had been very prominent in dreams as well as in his waking life; at this time individual elements became more conspicuous in his dreams, and the associations to these revealed important details of his actual life. This change, however, was not brought about by lexicographic interpretation of the symbols.

Another frequent misapplication of Freud's study of dreams is based on the fallacious theory that therapeutic success parallels the amount of correct interpretation of either dream or psychotic content. The Interpretation of Dreams is a fundamental contribution to our basic knowledge but not a model for therapeutic technic. We often forget the hint of Ferenzi, who sometimes asked psychotic patients to interpret dreams of neurotic patients which he himself could not understand.

A similar fallacy, and one which has obstructed many promising investigations, is the idea that the analysis of what a psychotic person is thinking is equivalent to a demonstration of why he is psychotic. Even so important a study as Tausk's analysis of the meaning of the influencing machine did not show why the patient was incapable of a social adjustment or why he believed the source of his strange sensations existed in the outer world. The hysterical patient's fantasies about the typewriter represented the same wishes as those of Tausk's psychotic patient. But the neurotic patient had repressed her association of typewriter with her genital sensations. And she had not lost her capacity to discern reality values: she had not ascribed her fantasies to a machine which did not exist, and though her typewriter was indeed an object of unconscious sexual value for her its reality and utility were also clearly recognized. The most significant fact is not that both this

hysterical and that schizophrenic person ascribed genital sensations to a machine but that the psychotic patient had lost his capacity to appreciate and test the reality of these fantasies. This lack of an essential function for social adjustment and not the details of his sexual fantasy must be the object of an investigation of the etiology of his psychosis.

I myself⁷ have emphasized that, although the content and structure of hallucinations and delusions are identical with dream thoughts, it does not necessarily follow that the sleeper and psychotic are therefore adapting to the same problems. Psychoanalysts are familiar with the fact that patients during analysis occasionally report dreams in order to conceal their strongest motivations. Possibly schizophrenic thought is like this type of dreaming; for very probably wishes represented in the autistic thought of the schizophrenic patient are not the same as those which disturbed his relations to reality. Yet it is too often assumed that analysis of a schizophrenic patient's fantasies is equivalent to an explanation of his psychosis.

STUDIES OF PARANOID IDEAS

Two of Freud's other discoveries in his studies of dreams and neuroses also led to specific knowledge of the mental symptoms of paranoia: these were the existence of unconscious homosexuality and the mechanism of projection. The dreamer perceives an image which arises in his mind without external stimulus as though it existed in the outer world. In the classic Schreber case Freud⁸ showed that this mechanism of "projection" is pathognomonic of paranoia and—I may add—of every item of normal and abnormal mental life which we characterize as "paranoid," when one's own fantasy or idea is ascribed to some one else. But Freud went further than the description of the mechanism of projection in his analysis of Schreber. He showed that the need to project coincided with an unconscious need for homosexual love which, though of overwhelming intensity, was originally denied by the patient's conscious mind. Still more amazing was Freud's discovery that this was true not only of such cases as the case of Schreber, whose delusions concerned people of his own sex, but that unconscious homosexuality was also the responsible drive in paranoid delusions concerning a person of the other sex.⁹ This is a discovery which has not only illuminated this important group of psychotic symptoms but has also led to our recognizing the dynamic importance of unconscious homosexuality in many types of criminal behavior, obsessional neurosis, alcoholism and a multitude of other psychologic reactions normal and abnormal.

This work on the paranoid delusion has been carried out in more detail by other analysts, including Stärcke,¹⁰ van Ophuijsen¹¹ and Feigenbaum.¹² They have shown the close intimate relationship of paranoid symptoms to infantile fantasies which personalize feces and consider them animistically as dangerous beings which threaten

the individual. Abraham¹³ then showed that this was related to a stage of development at which the emotions are centered on a body part of the object rather than on the person in his totality. The paranoid psychosis, according to Abraham, resembles certain phases of melancholia in that the patient's fantasies show a desire to incorporate the object; but it differs from melancholia in that the hostility is directed against a part of the object rather than the whole (breasts, penis, buttocks, hair, feces) and also in the prominence of fantasies that this incorporated part object can be destroyed and eliminated by defecation. Klein¹⁴ and Schmiedeborg¹⁵ have recently carried this line of research still further, especially by adding to our knowledge of the relationship of very primitive fantasies of aggression to anxiety and projection. The clinical facts which emerge from all these studies of paranoid reactions are: (1) the constant relationship between paranoid symptoms and active anxiety-threatening desires for homosexual experience, even when the manifest delusions refer to people of the other sex—as in delusions of jealousy; (2) the nature of projection: the patient denies certain ideas and ascribes them to other people; (3) the close relationship of this mechanism of projection to fantasies of coitus per ano and to a group of animistic ideas that feces act like hostile people or, more exactly, like parts of people whose totality is regarded as hostile. But we must still raise the question whether Freud, if he had originally sought to explain the facts of the Schreber and confirmatory cases after the ego had become a major object of analytic study, would have offered the theory of the "transformation of instinct" to explain the relation between the homosexual wish and the conscious "delusion" of hostility. For, in striking contrast to his reports of neurotic cases, Freud deals only with the period of Schreber's life when he was psychotic and has not analyzed the childhood and development of the man. The reason why the homosexuality of this and other paranoid patients had become so intensified was not investigated. The discovery of the activity of homosexuality in the paranoid has therefore helped us immeasurably to understand the mechanism but not the cause or origin of the psychosis.

"OBJECT LOVE" IN PSYCHOSES

Psychoanalysis has not clarified the etiology of psychoses (except some cases of depression¹⁶) to any such degree as it has the etiology of psychoneuroses. The first important contribution which distinguished between psychotic and neurotic mechanisms from more than a descriptive point of view was an early paper by Abraham.¹⁷ He pointed out that the hysterical person's fantasies represent genuine sexual wishes for certain people even when the satisfaction of these in behavior is neurotically denied, while the fantasies of schizophrenia disclose a substitution of various parts of oneself for interest in an object. Freud elaborated this observation in his chief theoretical contribution to the

etiology of psychosis. In his paper "On Narcissism,"¹⁸ published in 1914, he concluded that the primary process of psychosis is an incapacity for normal emotional interest in other people and things. The psychotic do not need to love others in a normal way, while the psychoneurotic do need to love others, but this basic need involves them in an emotional conflict and an unconscious repetition of infantile relationships. Freud assumed that the need to love, which he called the "libido," is a biologic constant. The psychotic process, therefore, does not involve a depletion of the total libido but a redistribution of the proportions of libido which determine object love and self love. This theory of the psychotic process is very like that economic theory of the financial depression which states that it was not a consequence of insufficient wealth but of the abnormal distribution of wealth. In psychosis, therefore, the love of persons and other social relationships are impoverished, and the energy withdrawn from these produces an abnormally excessive interest in bodily functions and psychic attributes of the self. In the schema I attempt to visualize this idea that every individual's total need to love is distributed in varying proportions among three classes of objects, one object being the self.

"Normalcy," psychoneurosis or psychosis is not, therefore, established by absolute criteria but by the dominance of normally gratified object love, conflict producing object love or introvert pleasure, respectively.

Freud continues that many of the more obvious symptoms of psychosis are secondary to this primary loss of the need to love others; they are very rudimentary and primitive efforts to reestablish such an interest in others. The evidence which impresses him most forcibly is the psychotics' use of words, in which their emotional interest is in the verbal symbol itself and not, as in normal adults, in the object which the word represents. Freud had long before recognized that dreams represent a prelogical way of thinking and spoke of this as a "regression" to an early stage of mental development. Such a regression is apparent not only in the thinking of the psychotic but in their means for finding pleasurable experience. A psychotic regression, therefore, would ultimately reach a stage of which intra-uterine life is the prototype; it is a stage reexperienced normally in sleep. A sleeping individual, baby or a psychotic person who is functioning in this way derives his pleasure chiefly from his own sensory experience and is not dependent on reciprocated feelings for other people.

In the psychiatric hospital the clinician does not generally see the observable manifestations of this regression fully developed except very probably in stupors and in some suicides, especially those suicides which are acts representing wishes symbolically.¹⁹ But there is sufficient evidence of it in most profound psychoses to lend empirical support to the theory. Various types of intra-uterine and birth fantasies, expressed in words and behavior, are abundant. The conspicuous elements of most clinical pictures are, however, a complicated assortment of fragments of the intact personality, of incomplete phases of the psychotic regression, and of efforts at restitution. We see clinical evidence in great abundance, however, that the personality is functioning at levels of the first years of extra-uterine life, as in the

need for tube feeding, incontinence, feces eating, non-organic masturbation and also in many infantile activities not obviously related to the erogenous zones, such as studying and experiencing the body parts as ego-alien objects, falling, primitive drawing, and block-building. Infantile thinking processes are, moreover, always conspicuous in delusions and motor speech.

Psychosis also always illustrates the primary feature emphasized by Abraham and by Freud—the incapacity for normal emotional relationship with others. In some of the less severe cases only a fraction of the personality is affected and the capacity for normal socialization has survived to a considerable extent. In still others, such as socially adjusted paranoid psychoses and some schizoid people, there is a very complete semblance of normal interpersonal relationships, and no everyday clinical experience is more amazing than the communication by such people of primitive fantasies, anxieties and our consequent recognition that apparent "normalcy" has been chiefly a shield which excludes others from participation in the subjectively vital aspects

Distribution of Libido

Psychiatric Description	"Normal" Trends, plus:	Psychoneurotic Trends, plus:	Psychotic Trends
Total libido	objective love gratified in (1) sexual life, friendship and social relations, and in (2) sublimations (work, art, play)	object love involved in inner conflict: apparent in character traits, sexual and social frustrations, and neurotic symptoms	overvaluation of self; apparent in hypochondriacal and megalomaniac trends, objectless auto-erotism, symbols, and mentation in which words are more important than people and things

of their conscious experience. I think, however, we should be warned by Freud never to ignore the depth of the regression in a psychotic mechanism merely because it is not clearly evident to the observer, whose attention is easily distracted by the normal or neurotic aspects of the total picture.

Perhaps the greatest importance of Freud's paper on narcissism for other investigators is the warning not to assume that the nature of psychosis can be understood by analysis of the symptoms. His conclusion is that delusions, hallucinations, behavior and other diagnostic criteria are secondary phenomena which seem to him to be rudimentary efforts to restore the lost feeling for objects. This concept parallels his more complete distinction between hysterical paralyses or obsessions and the basic conflicts of adult and infantile wishes which constitute the primary process of neurosis. It is Freud's nearest approach to an adequate discussion of the etiology of psychosis.

THE EGO IN PSYCHOSIS

But Freud has given us yet another hint, which future investigation may prove to have been prophetic. His work on psychoneuroses had already shown that the emotional conflicts which culminate in neurotic suffering were conflicts between infantile wishes, generally unconscious, and adult attitudes. They are, therefore, primarily conflicts within the personality, though they secondarily affect environmental relations. In his paper on "Neurosis and Psychosis" (1924) Freud²⁰ concluded

18. Freud, Sigmund: On Narcissism: An Introduction, 1914, translated in *Collected Papers*,² vol. IV.

19. Hendrick, Ives: Wish Fulfilment as a Motive for Suicide, read before the American Psychoanalytic Association, Dec. 29, 1936.

20. Freud, Sigmund: Neurosis and Psychosis, translated in *Collected Papers*,² vol. II.

that the conflicts which result in psychotic adaptations are primarily conflicts between the individual and his environment. Freud himself has not gone very far in answering the question it raises: Why are the psychotic different from neurotic people, in their inability to deal with the problems of reality by endeavor, and the problems of tabued impulse by neurosis? But in his *Introductory Lectures*²¹ (1914) he explains this view a little more fully:

I have taken you to the point from where the next steps forward in analytic work are to be expected. Since we have ventured to use the concept of ego-libido, the narcissistic neuroses [i. e., psychoses] have become intelligible; it has resulted in the task of seeking a dynamic explanation of these conditions and at the same time of extending our knowledge of mental life by understanding the ego. Ego-psychology, itself, which we are working at, cannot be founded upon the data of our self perceptions, but, like the libido, upon the analysis of disturbances and disorganization of the ego. We will probably think less of our present knowledge of the libido processes, when this greater work has been performed.^{21a}

It is the idea embodied in this paragraph which I wish to stress and not Freud's preoccupation at the time with a theory of ego instincts which he himself later explained²² was superfluous. It is essentially the idea of that later paper which distinguished between psychotic and neurotic conflicts; it is the idea that psychoses are not, like neuroses, primarily adaptations to sexual conflict. They are adaptations to defects in the integration and efficiency of those functions essential to real relations with people for both pleasurable and egoistic reasons, and of those functions essential to the control of excessive infantile needs by either normal or neurotic mechanisms. Because many of a psychotic person's acts do gratify needs which are normally dominant during the suckling stage of development, some analysts have been content to explain psychosis as a "fixation" at the oral stage. But Freud in the passage quoted implies that such an interpretation is a makeshift, necessary only so long as our knowledge of the ego is inadequate.

During the last decade, analysts have given special attention to the investigations of the ego. But these studies have been based chiefly on observation of the "defense mechanisms" utilized by neurotic patients in avoiding the guilt or anxiety which accompanies certain phases of analysis. These have extended our knowledge of these reactions of a relatively mature and normal ego to infantile and other tabued impulses, which were described by Freud in 1923.²³ But they have not yet thrown much light on the early development of the ego itself and that is the basic problem in the psychology of psychosis.²⁴ Thus Anna Freud²⁵ has recently suggested that anxiety, which is a response to the intensity of emotional drives irrespective of their specific aims, is characteristic of puberty and of the early stages of psychosis. But the incapacity to discharge such drives before such a degree of general emotional tension is attained is a question which leads again to the problem of inadequate or immature ego

function.²⁶ Wälder²⁷ has come closer to this basic problem of psychosis in his description of the "multiple function of the ego"; he discusses the principle that a reaction of the personality as a whole is an accommodation to many functional requirements. In psychosis, one essential function, the successful adaptation to the environment, is always absent, and obviously the total personality of the psychotic individual does not fulfil Wälder's criteria in this respect. Nünberg has contributed the most so far to this problem, in his studies of catatonia,²⁸ and of the failure of the "synthetic function" in psychoses.²⁹

Discussion of the "ego" sometimes locks more doors to knowledge than it opens. For the concept of the ego in psychoanalytic literature is an extremely broad generalization and it is easy to substitute the abstraction for the constant array of clinical and everyday facts which the concept summarizes. These facts comprise all psychologic events which show a useful organization. "Ego" includes perceptual experience, organized "knowledge," which functions in determining a choice of reactions. "Ego" includes intelligence, the discrimination between perceptions, possibilities and courses of action. It includes all our organized behavior, the means we adopt for influencing the outer world effectively or turning it to our advantage. It includes all methods of control—voluntary and involuntary—over our impulses, over the primitive, unorganized emotional demands for action, and the organization of these impulses in social relations, work and play. And it includes both normal and abnormal defense mechanisms which prevent the immediate and direct gratification of many impulses. The ego comprises, therefore, the organization of perceptual experience, the organization of impulses for executant acts and the denial, delay and transformation of impulses which may prove injurious reactions or provoke anxiety. Its functions ensure self preservation, adaptation to reality and adequate gratification of the needs for pleasure and self assertion. These functions maintain emotional tension and anxiety at a minimum level, while ensuring relationships with the real world. The ego is the sum total of adjustments between a personality and its environment. The "ego," therefore, includes all which other psychologic schools have called the "integrations"; the psychoanalytic concept differs only in its view that the intelligent and conscious control of these integrations is limited. It offers its own evidence that many aspects of the ego are as unconscious as many impulses, motives and fantasies. Again, in the study of the ego the unique point of view of psychoanalysis is chiefly its respect for the unconscious.

One may clarify the psychoanalytic consideration of the ego in psychosis and suggest its clinical applications by tabulating some of the more obvious differences between psychoneurotic and psychotic personalities.

We then see that the following are some of the differences which distinguish psychosis: 1. Objectless pleasures predominate. 2. The aggressive impulses of the psychotic are more purely hostile, the reality of the object plays less role in their fantasy derivatives, and the evidence of ambivalence and of that unconscious love

of the hated object, or unconscious hate of the loved object, which are manifest in "sadism," is less than in neuroses. 3. Anxiety reactions to infantile impulses in psychoneurosis are usually highly organized, with moral and ideal components, and well rationalized; they are in consequence generally experienced as inferiority feelings, failure, guilt, and the like. Even neurotic phobias, where the anxiety is manifest, show considerable organization in that the anxiety is ascribed to avoidable reality situations, and the reality testing of the anxiety is not abolished. But in psychosis the anxiety is not well rationalized except by delusions. In neurosis the anxiety usually is associated with repressed fantasies of sibling and parent rivalry—a three-person pattern; while in psychosis anxiety is more often a reaction according to the "talion principle"—a two-person pattern, with the expectation that the object of an aggression will automatically retaliate in kind.

The efficiency of the neurotic person's ego is often greatly damaged by the activity of guilt, anxiety, and character defenses; yet thorough analysis will show that the essential functions are intact and highly organized. The ego of the psychotic differs in the following ways: 1. Reality testing is greatly impaired, so that delusions and other autistic fantasies are conspicuous. 2. The self-preservative functions are often inadequate for obtaining food or for protection from environmental dangers. 3. The capacity for useful self assertion is absent, greatly impaired or delusionally oriented. 4. The "defense mechanisms" which are organized to protect the personality from infantile needs which evoke anxiety or guilt are in general simpler and more primitive; they impair rather than facilitate real and useful interactions with the environment.

Repression is the defense mechanism which has been most thoroughly studied by analysis and seems to be the most constant and important one in typical neuroses. But its role in psychosis is a subject of considerable debate among analysts. If, however, we restrict our discussion to generally agreed facts it is indisputable that some distortion of conscious content and concealment of real content is to be observed in psychoses as well as in neuroses. On the other hand, many psychotic persons are conscious of—they even just "take for granted"—many things which both normal and neurotic people repress. The meaning of sexual symbols is often immediately evident to them. A psychotic may think unrealistically when he believes a flick of a man's finger will kill him; but, at the same time, he has, like the infant, recognized aggressions in another of which a normal man would be unconscious or to which a normal man would not, like the psychotic, ascribe their full, primitive, emotional values. Many psychotic people disclose unrationalized conscious bisexual, pregnancy and castration fantasies, and incestuous and homicidal desires. Whether or not one regards these facts—as I do—as clear evidence that the function of repression is not normally effective, it is certain that it does not influence conscious content, emotional experience and behavior in the same way, or to the same degree, as it does in either neurotic or normal people. To say that normal repression is absent or defective, or to say that in the psychotic one sees a more primitive, less highly organized type of repression, is a quibble of words, not of meanings. How, then, can one hope to explain a psychosis by analysis of repressed wishes, when the pathologic material so clearly shows the inability to adjust to infantile demands by repression, by even so

imperfect a mechanism as that which is so conspicuous in the development of neurotic problems.

Work of the last decade has familiarized us with a variety of other defense mechanisms in psychoneurosis, especially the complex character patterns which serve as defenses against anxiety. Of special interest to students of schizophrenia is that reaction to painful situations by inappropriate affects which Anna Freud²⁵ has recently described as a normal mechanism of childhood. The essential point, however, is that the psychotic are like the neurotic, in that they also need to adapt in such a

Comparison of Psychoneurosis and Psychosis

	PSYCHONEUROSES	PSYCHOSES
"Sexual" (pleasure) needs	Ultimate goal, object love: mating, "aim inhibited" love, play	"Narcissistic" goals: extreme overevaluation of self, pleasure in primitive sensations and thought, symbolic and auto-erotic gratification
	Regression to infantile objects and fantasies	Regression to preobject pleasure
Aggressive needs	Competitive, ambivalent, sadistic	Hostility more primitive, unrealistic, often projected
Self preservative needs	Normally organized in physiologic functions (nutrition and living) and in behavior protecting against real environmental danger	Organization against environmental danger more or less defective; sometimes protection of life defective
Anxiety reaction to infantile pleasure seeking and aggressive impulses	Experienced as reality tested phobias, and as organized inferiority and guilt feelings	Primitive, unreal, less rationalized, typically according to "talion principle"
Useful self assertion	Normal or limited by neurotic anxiety	Absent or delusionally oriented
Reality testing	Intact, though imperfect	Greatly impaired: delusions, hallucinations, and other autistic fantasies and behavior conspicuous
DEFENSE MECHANISMS (against infantile needs evoking anxiety and guilt)		
Repression	of most infantile fantasies, motives and associated emotional values; rationalization conspicuous	Defective: conscious knowledge of infantile motives, symbols, behavior and associated emotional values which are normally unrecognized; some distortion and denial, but not typical repression
Character patterns	Often predominant	Often defective
Primitive defenses: flight, inhibition, projections	Always present	Predominance very manifest
Identifications with authorities and ideas ("super-ego")	Parental and social tabus largely controlled by guilt	Guilt often defective; fear of detection and retaliation more manifest
Primitive identifications (not well studied)	Normal role in development	Probably defective or defectively organized

way as to avoid anxiety experiences. In contrast to the neurotic, however, their adjustments depend on the more primitive types of defense, those which normally predominate before a high degree of personality organization is attained. The most important of these less organized defenses are flight, shown in the social withdrawal of the psychotic; the simple inhibition of impulse, which is very apparent in their defective capacity for normal self assertion, and projection, which is apparent in many of their delusions. These are much less highly organized defense mechanisms than repression and are derived from much more primitive phases of development.

In the development of the ego, the adoption and organization of patterns whose elements were originally perceived as details of other people's behavior play a very important role. We call these "identifications";³⁰ they are reactions to emotional relations with other people and play a conspicuous role in development. Their importance in both normal and neurotic people has so far been chiefly demonstrated by analysis of the development of the "super ego";³¹ the prohibition attitudes of authoritative people are made permanent components of the personality and result in effective intrapsychic tabus of infantile impulses, irrespective of environmental restraint. When they have been established, their violation is experienced as guilt. The role of guilt in psychosis is as hotly debated by analysts as the role of repression. But the facts of preternatural capacity to understand infantile desires and to gratify them without painful subjective reactions seems to me factual evidence of a defective organization of those identifications responsible for the experience of guilt. I think that many reactions which are loosely interpreted as evidence of guilt are a perpetuation of the childhood fear of actually being caught, before the child has developed a genuine conscience; so long as the "sin" is unknown to others, the consequences are not unpleasant. This fear of detection by others, rather than the real guilt of later childhood and maturity, is more conspicuous in the social reactions of the psychotic than of the neurotic.

PRIMITIVE IDENTIFICATION AND THE EGO

I have discussed elsewhere²⁴ my opinion that the capacity for normal executant functions, and for repression, are also end results of the organization of identifications with the behavior of other people. But these identifications are more primitive and occur much earlier in life than those from which the ideals and moral sense are constructed. It seems to me that the early identification with executant patterns of people in the environment is probably essential to the development of an ego which can deal effectively with special stresses of adult life by either normal or neurotic adaptations. The person who adapts by psychosis is one who has not adequately achieved such organization of his very early behavior patterns through identification and cannot defend himself adequately against the anxiety incident to unusual emotional stresses. This is still a hypothesis, because analysis has not studied, or even discussed, the early development of the ego. It can offer little knowledge which would parallel Freud's and Abraham's reconstruction of the earlier stages in the development of sexual feeling, sensory pleasure and object love.³² It is only those later identifications which become the super ego which have been intensively investigated. Possibly this is not an oversight but the inevitable consequence of concentrating on those observations for which analytic technic is especially adapted.

But I can illustrate the role of primitive identification by the development of language. The infant is biologically endowed with an ability for and a pleasure in uttering sounds. He practices his phonetic repertory until his ability to control the utterance of consonants and vowels is fairly well developed. This provides him

with an instrument which at first has no social utility. When verbal intercourse with others is possible and desired, it is by using the words of other people that it is achieved. Piaget³³ has shown the elaborate development of language in later years of childhood (chiefly after the age of 4) and its intimate relation to the need for social experience. I recently observed the intimate relation of social need and language development in a child of 2. One day she appeared unusually melancholy; she then uttered and kept "verbigerating" the first full sentence of her life: "Ma-ma go-go do-do" (Mama went out the door). Apparently her unusual emotion, occurring at a time when her potentiality for the use of language had matured, had produced this rhetorical achievement. One casual observation proves nothing. But it can at least illustrate what I mean by the role of primitive identifications in the development of executant functions. The utilization of a capacity for language begins as a response to an interpersonal situation and the effective response is achieved by adopting the phonetic configurations of other people and putting them together in the same way, when this becomes of value. Similarly the schizophrenic patient to whose dream material I have referred discontinued his superabundant use of symbolic expressions and began to talk consistently in my language when his behavior showed a new and strong need and capacity for personal relationships.

The development of motor patterns parallels that of language. The infant can be observed³⁴ in his gradual progression from random movements to directed ones, which unit by unit become the potential tools for motor mastery of the environment. Is not the further organization of these rudimentary capabilities into useful motor abilities also, like language, impelled by his social needs and achieved by primitive identifications? A detail of the process could be observed in the play of two 2 year old children. A was striking B's head violently with a block. A's behavior was not exactly like that of a committed psychotic; it was more like the mental status of a scientist engaged in research, for he showed intense and studious interest in the peculiar reactions of his little guinea pig but no sign of affection or sympathy with her experience. B first reacted by defending herself and then by attacking A's head with another block; she was distressed and frantic. Suddenly B stopped, fixed A's attention with her eyes, and began hitting her own head with her own block. A caught on, began striking his own head instead of hers, and in a few moments they were dancing up and down gaily, striking themselves and giving every evidence of delight in discovering a new game to play together. What psychotherapeutic genius had shown B how to convert a psychopath into a jolly good fellow in a few seconds? Didn't her success illustrate the very essence of social adjustment? Indeed, she had glimpsed and applied the thesis which Freud³⁵ elaborated at the climax of his career in "Civilization and Its Discontents": that hitting oneself instead of attacking is the price of mutual fun; that the conversion of aggression into masochism is prerequisite to civilized life. But the point of my illustration is that A had learned to like B and incidentally to transform his primitive aggression into socialized play without retaliation anxiety by reproducing B's motor

pattern. Only when he identified with this motor pattern was his "little psychosis" cured. Similarly, a psychotic adult is unable to communicate anything except very superficial remarks for a long time and intense hostility is manifest in many ways. After prolonged subjective struggle, he succeeds in using my fountain pen to write; he then is able to reveal his intimate thoughts.

It is such rudimentary identifications, and their complex organization in the course of development, which most of the psychotic have not fully achieved. The psychotic do not adequately differentiate external from internal perceptions, rational from autistic thought. They are usually unable to take care of themselves independently in an ordinary environment, and in many cases even the most elemental self-preservative functions, such as obtaining nourishment and avoiding death, are abolished. These are very different adaptations from those observed in neuroses. Whereas most neurotic characteristics disclose one or another type of excessive tension, a hyperprotective ego or an excess of anxiety and love seeking, the psychotic often live without these things—sometimes very pleasantly. It is not impossible that even our customary formula that the psychotic retreat from painful reality to pleasurable fantasy is putting the cart before the horse: that actually they must fantasy in their autistic way, that their failure to deal with reality is a consequence of their defective ego, not its cause. There is much to indicate that psychosis may not be the best adjustment of well organized defense reactions to a difficult emotional problem but primarily an incapacity for useful executant functions. It is the study of such early stages in the organization of perception, language, motor and social patterns which is needed in the study of psychosis. We have understood much of what the psychotic are able to do without such knowledge. Psychosis, however, is not entirely a problem of too much fantasy, too much repression, too much guilt, too much inner conflict, but fundamentally a problem of inadequate organization. Further understanding, and possibly etiologic therapy, awaits further knowledge of the primitive ego of the child, the phases and mechanisms of its development.

CONCLUSION

Freud has shown that psychosis is a purposeful adaptation, that psychotic ideas are meaningful and not chaotic but are controlled by prelogical types of thinking; that the pleasure needs of psychotic people are of the infantile preobject type. He has emphasized the theory that delusions, hallucinations and the special use of words by the psychotic repeat the infant's rudimentary efforts to establish an interest in external things. He warns us not to confuse the more conspicuous symptoms with the fundamental psychotic process. He has made this point still clearer in his statement that psychosis is primarily an incapacity to deal effectively with the environment and not, like neurosis, a consequence of conflict within the personality; and in his opinion that psychosis is the consequence of abnormality of the ego. The layman says the same thing when he uses such expressions as "A nut is missing" or "That fellow is not all there." What "is not all there" is his capacity to transform primitive drive into socially useful function, and it is the developmental history of such capacity that clamors today for adequate study and for new approaches.

Clinical Notes, Suggestions and New Instruments

SEGMENTAL SCLEROSIS OF THE SAPHENOUS VEIN FOR VARICOSE VEINS, ULCERS AND DIMINISHED ARTERIAL SUPPLY

GERALD H. PRATT, M.D., NEW YORK

The advantages of the combined ligation and injection of the saphenous vein in the treatment of varicose veins and ulcers over previous therapeutic measures has been generally accepted. Experience has shown certain disadvantages that require technical changes and improvements. The original method did not provide for a uniform sclerosis, and this important addition to provide an evenly segmented sclerosis and to eliminate local reactions is presented. In the vascular service of the New York Post-Graduate Hospital (Columbia University) in the last twenty-four months the technic developed for this method has proved most satisfactory and has eliminated the morbidity and

Fig. 1.—Section through point of injection of sclerosing solution into rabbit's ear two weeks after injection. Notice the degree of fibroblast proliferation.

local slough previously experienced. The results in most instances have likewise eliminated the necessity for local injections at a later date.

Only two contraindications to the procedure are made: the presence of an incompetent deep venous circulation and a recent acute phlebitis. Ulcers respond readily and are not a contraindication. Contrary to the general conception, we have found that many in the group with a defective arterial supply are clinically improved after associated varicose veins have been eliminated.

METHOD

After infiltration with 1 per cent procaine hydrochloride, injected through a single wheal at the fossa ovale, the saphenous vein is exposed through a transverse incision at its junction

From the Vascular and Surgical Service, New York Post-Graduate Medical School and Hospital (Columbia University).

with the femoral vein. The three main branches are sectioned (superficial circumflex iliac, superficial external pudendal and superficial inferior epigastric). The saphenous vein is divided at the femoral junction and the proximal end is ligated by a transfixion suture. The distal end is then opened and a ureteral

slough which accompany the introduction of a large amount of sclerosing solution at the one point.

The amount of solution introduced depends on the lumen of the vein, the number of varicosities, the condition of the ulcers present and the condition of the patient, but in general it should be large. From 30 to 50 cc. of solution is used as a routine, and with this method of segmental sclerosis larger and stronger doses of the drug can be used. As a rule guide I inject 5 cc. for each 5 cm. of catheter withdrawn. The catheter can be felt subcutaneously; figure 3 shows the x-ray appearance of the catheter in the vein being withdrawn as the solution is injected.

Technically, the catheter slips readily down the lumen of the vein. It may strike a valve, but with a slight turn and gentle

Fig. 2.—Section through same rabbit's ear 1 inch from point of injection. Notice that there is less fibroblastic replacement and some retraction.

type catheter is introduced for a distance of 60 cm. A sclerosing solution (from 20 to 60 cc. of 3.5 per cent sodium ricinoleate) is introduced as the catheter is withdrawn, thus equalizing its distribution throughout the length of the vein. The distal end is ligated with a transfixion suture and the wound closed without drainage. Because of its proximity to a source of contamination by the scrotum or labia, the wound is carefully sealed, a layer of white shellac being applied over the final adhesive covering to make it water tight. The patient immediately walks to aid further in the distribution of the solution, and a pressure pad is applied to any surface redness which indicates too great an accumulation of the sclerosing solution.

The necessity of introducing the solution uniformly and at many points of maximum intensity is illustrated by the photomicrographs shown in figures 1, 2 and 5. Figure 1 shows the sclerosis in a vein of a rabbit's ear at the point of introduction two weeks after injection. Figure 2 shows a point approximately 1 inch from the site of injection and shows that there is much less fibrous change. There are many capillary spaces that facilitate recanalization. Figure 5 shows a section of the same vein 2½ inches from the point of injection and indicates that the wall has not been affected. The degree of sclerosis is thus inversely proportional to the distance from the point of injection. The catheter method permits an equalized distribution of the points of injection throughout the vein, with infiltration of the main branches. Besides effecting a complete sclerosis, this method eliminates the periphlebitis, cellulitis and

Fig. 3.—Appearance of catheter in saphenous vein being withdrawn as sclerosing solution is injected.

pressure it will pass by. The possibility of the solution in the catheter sclerosing the deep venous circulation through a communicating branch is more theoretical than actual and is not

Fig. 4.—A, varicose ulcers of eight years' duration, with large tortuous veins. B, same leg three days after operation, with ulcers partly healed. C, same leg twenty-one days after operation with ulcers entirely healed and veins obliterated (40 cc. of 3.5 per cent sodium ricinoleate was used).

as serious a possibility as if the solution were introduced all at one point. The withdrawal of the catheter would prevent all the sclerosing solution entering at one time. For sclerosis there must be stasis, and the deep vein with its valves, good wall tone and muscle support makes stasis impossible. The ability of competent veins to take care of strong dextrose solu-

tion introduced each day indicates that unless there is stasis there will be no serious damage of the wall. While other solutions can be used for the injection, the low toxicity of the ricinoleate salt preparation and the large amount that can be used seem to be sufficient reason for its employment until more effective solutions are developed.

Fig. 5.—Section $2\frac{1}{2}$ inches from point of injection of sclerosing solution, illustrating that there is no effect of solution on the lumen of the vein.

Figure 4A shows a typical varicose ulcer, open for eight years, with large tortuous, incompetent veins. Figure 4B shows the same patient three days after administration of the therapy described. Forty cc. of 3.5 per cent sodium ricinoleate was introduced evenly by catheter method throughout the course of the saphenous vein. Obliteration of the veins and the healing effect in the ulcer should be noted. Figure 4C shows the same patient twenty-one days after treatment, showing the healed ulcer.

Dilated veins with their stagnant pools of deoxygenated blood are eliminated, ulcers heal quickly, the color and function of the leg improve and at times the arterial circulation is accelerated. Detailed results of the procedure are given elsewhere. Because of its construction with a large eye, the usual ureteral catheter frequently bends. A longer catheter with round end and a sprinkler type of opening for injection has been constructed and with its careful gradations is more effective for this work.

I would emphasize:

1. Infiltrations of 1 per cent procaine hydrochloride through a single injection site.
2. Division of all branches of the saphenous vein at the fossa ovale, except the lateral and midsuperficial femoral cutaneous, which should also be sclerosed.
3. Transfixation of the proximal end of the saphenous vein after division at the femoral junction.

4. Retrograde segmental injection by from 20 to 60 cc. of 3.5 per cent sodium ricinoleate while a catheter introduced for a distance of 60 cm. is being removed.

5. Careful sealing of the operative wound.

6. Ambulatory treatment thereafter.

I believe that this procedure eliminates two serious disadvantages in the use of the ligation and retrograde injection therapy; namely, the severe inflammation or suppuration at the thigh proximal to the injection point and the incomplete and nonuniform sclerosis in the vein.

OCCUPATIONAL LEUKODERMA
PRELIMINARY REPORT

EDWARD A. OLIVER, M.D., CHICAGO; LOUIS SCHWARTZ, M.D.,
AND LEON H. WARREN, M.D., WASHINGTON, D. C.

A leather manufacturing company recently reported that certain of their Negro workers who wore rubber gloves were becoming depigmented over the areas on the hands and forearms covered by the gloves. An examination of the workers showed that all of them, Negro and white, who wore a certain brand of gloves were affected not only on the arms but several of them on the covered parts of the body (figs. 1 and 2).

A similar condition was found in other tanneries, plating works, electrical apparatus manufactories and all other places investigated where that particular brand of gloves was worn.

The ingredients used in the gloves and the method of their manufacture were obtained from the company making them.

Fig. 1.—Depigmentation of forearms as a result of the wearing of rubber gloves.

Patch tests performed on the affected workers with the chemicals in the gloves showed that an antioxidant caused positive reactions on all of them, and after a few days when the inflammation subsided there occurred a definite depigmentation at the site of the reaction but no scar formation. The antioxidant is known by the trade name of Agerite Alba and is said by the

rubber company to be mono benzyl ether of hydroquinone containing less than 1 per cent of unchanged hydroquinone.

The rubber company withdrew the antioxidant from the glove formula and the workers are becoming repigmented since they ceased wearing the gloves containing the antioxidant.

A review of the literature fails to reveal any report of a similar condition in man, but in 1936 Oettel¹ reported that when he fed hydroquinone daily to black-haired cats in doses of 30 mg. per kilogram of body weight the hair turned gray after a period of from six to eight weeks, and it required a similar period for it to become repigmented after the administration of the drug was stopped.

In view of these observations it is recommended that this antioxidant should not be used in rubber articles for wear until further research has developed methods of control.

Fig. 2.—Depigmentation occurring on forearms, upper arms, chest, abdomen and thighs.

The mechanism of the depigmentation and the physiologic action of the chemical on animals and human beings is now being studied with the view to determining if possible its safe usage in dermatology. When our work is completed a detailed report will be submitted.

The Path to the Ph.D.—The *fons et origo malorum* of the weaknesses of literary scholarship are probably the graduate schools. The graduate schools persistently refuse to follow the example of the law schools and the medical colleges, who, by rigidly refusing to admit merely mediocre students, have immensely elevated intellectual standards. In most instances, however, anybody with any sort of a B.A. degree can enter a graduate school somewhere, whether he is qualified for a scholarly career or not. He can also in most instances acquire some sort of a higher degree and in time increase the amount of useless information. Graduate schools are not opposed to brilliance, but they are tender of mediocrity with its white flower of a blameless life, with the result that inertia and the grade of B get hundreds of students so far along the path to the Ph.D. that it is cruel and unusual to cut them off at the last mile from this sweet fruition of an earthly crown.—Jones, Howard Mumford, *What's the Matter with Literary Scholarship?* *Saturday Review of Literature* 19:4 (March 18) 1939.

Special Article

THE PHARMACOPEIA AND THE PHYSICIAN

THE USE OF DRUGS IN OPHTHALMOLOGY

SANFORD R. GIFFORD, M.D.

CHICAGO

This is one of the second series of articles written by eminent authorities for the purpose of extending information concerning the official medicines. The twenty-four articles in this series have been planned and developed through the cooperation of the U. S. Pharmacopeial Committee of Revision and THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.—Ed.

Because of the large scope of the subject assigned to me, it will be possible to mention only the more important drugs for which definite indications exist.

INTRA-OCULAR INFLAMMATION

One definite function that may be served by drugs is paralysis of accommodation during periods of active inflammation affecting the internal structures of the eye. Placing the ciliary body at complete rest is of great value in the relief of pain and in the promotion of natural healing processes. A second object of treatment is to cause dilatation of the pupil, which breaks up or prevents adhesions of the iris to the lens and the formation of a membrane which would occlude the pupil and give rise to a secondary rise of intra-ocular tension. Both these objects are achieved by the group of drugs known as cycloplegics, since most of its members are also mydriatics. The typical and most important member of this group is atropine. It acts by paralyzing the endings of the third nerve in the iris and ciliary body. It is absorbed through the cornea and to a lesser extent through the conjunctival vessels when instilled in the conjunctival sac. A 1 per cent solution of atropine sulfate is usually employed. Whereas the effect of one drop persists for from ten to fourteen days in the healthy eye, during active inflammation larger amounts frequently repeated are necessary, so that from three to five drops are often employed two or three times a day. The slower and more prolonged absorption of alkaloids from an oily base has led some ophthalmologists to prefer the use of 1 per cent atropine ointment. An amount equal to 2 or 3 minims (0.13 to 0.2 cc.) is squeezed from a small tube into the lower conjunctival culdesac, after which the eyes are closed. The use of the ointment at night combined with the solution during the day is sometimes of advantage.

When the pupil does not dilate freely with 1 per cent atropine, a 2 or 3 per cent solution may be tried but must be used with caution, since the drug passes into the nose and is absorbed, giving rise to symptoms of intoxication. It may be necessary to reinforce the effect of atropine with that of epinephrine and cocaine, a combination of salts of all three drugs being injected subconjunctivally. The amount so employed must be carefully measured and should seldom exceed 2 minims each of 2 per cent atropine sulfate, 4 per cent cocaine hydrochloride and epinephrine hydrochloride 1:1,000. Atropine, as is well known, has the property of raising the intra-ocular tension in eyes predisposed or already

From the Department of Ophthalmology, Northwestern University Medical School.

DRUGS IN OPHTHALMOLOGY—GIFFORD

subject to glaucoma. Hence it is important that the presence of glaucoma be excluded before atropine is given. It is equally important, however, that atropine be given at the earliest possible moment in cases of iritis or iridocyclitis, before permanent adhesions of the iris have occurred. Atropine is indicated not only in iritis and iridocyclitis but also in severe choroiditis and in keratitis, of both the ulcerative and the interstitial variety, since secondary inflammation or spasm of the sphincter iridis and ciliary muscle commonly occur in these conditions.

Atropine possesses several disadvantages and hence the use of one of its substitutes is indicated under certain conditions. Its prolonged effect is inconvenient in certain mild types of inflammation, which often subside within a few days. The same objection applies in conditions admitting doubt as to the diagnosis. Under these circumstances it may be convenient to employ homatropine hydrobromide in 2 per cent solution, the action of which subsides within twelve to twenty-four hours. Prolonged use of atropine produces in certain persons signs of sensitization, as shown by inflammation of the conjunctiva and skin, accompanied by severe itching. This calls for the use of a substitute such as scopolamine, the effect of which persists from five to seven days. Scopolamine is used in 0.5 per cent solution of the hydrobromide. When scopolamine is used it must be remembered that a marked psychic effect is produced by small amounts in certain persons, so that only one or two drops are given at a time, pressure being made over the lacrimal sac for five minutes after each instillation.

Of drugs given for their systemic effect in intra-ocular inflammation, the most important is the salicylic acid group. These drugs have the same effect here as in rheumatic fever, producing not only relief of pain but probably also a diminution of inflammatory changes such as congestion and swelling. Sodium salicylate is most often employed, doses of from 120 to 150 grains (8 to 10 Gm.) a day being given to an adult of average weight during the first few days of acute inflammation, after which from 60 to 90 grains (4 to 6 Gm.) a day may be continued for a longer period. Tinnitus and loss of appetite do not indicate a discontinuation of the drug, while when vomiting occurs three times a day, the appearance of albumin in the urine occurs not frequently and is an indication for decreasing the dose or discontinuing the drug. Many patients prefer taking the drug in capsule form, in which case a full glass of water should accompany each dose. Use of the liquid form produces less marked gastric irritation in some persons: sodium salicylate 30 Gm., aromatic elixir 45 cc. and sufficient water to make 120 cc. The dose is 2 teaspoonfuls in a glass of water four times a day. The use of acetylsalicylic acid in such large doses is more apt to produce gastric irritation. When it is employed, equal amounts of sodium bicarbonate lessen the discomfort; sodium bicarbonate is of less value when employed with sodium salicylate.

Of even more importance than use of the aforementioned drugs is treatment of the causative agent of intra-ocular inflammation. This includes the use of anti-syphilitic drugs in conditions due to syphilis and the removal of foci of infection when these are assumed to be of causative importance. In the latter conditions the streptococcus is often the causative agent and many reports indicate the value of sulfanilamide. From 50 to 60 grains (3 to 4 Gm.) a day may be given by

mouth on the first two days, after which the dose is reduced to 30 grains (2 Gm.) a day. The toxic properties of this drug demand watchfulness and care in its use, with determination of its concentration in the blood. It should be discontinued at once on signs of undue toxicity.

The use of local heat and injections of foreign protein, while important, will not be discussed here.¹

OTHER USES FOR THE CYCLOPLEGIC-MYDRIATIC GROUP

Cycloplegia and mydriasis for refraction are most conveniently accomplished in adults with homatropine hydrobromide in 2 per cent solution. Instillation of 4 drops at ten minute intervals usually brings about complete cycloplegia in sixty minutes after the first drop. The effect of homatropine may be hastened by its combination with amphetamine sulfate.² One drop of 1 per cent amphetamine sulfate given five minutes after one drop of 5 per cent homatropine hydrobromide produces satisfactory cycloplegia in from forty-five to sixty minutes.

To avoid the possibility that an attack of glaucoma may be precipitated by homatropine hydrobromide, it is safest to use one or two drops of a miotic after refraction is complete. One per cent pilocarpine nitrate or 0.2 per cent physostigmine sulfate is usually employed. For persons past the age of 40 this danger is somewhat greater and euphthalmine in 2 or 5 per cent solution, 3 per cent ephedrine sulfate or 1 per cent amphetamine sulfate may be employed instead of homatropine hydrobromide.

In children under the age of 10 or 12 the ciliary muscle is much more active than in older persons and often cannot be paralyzed by homatropine. Hence the use of atropine is required at this age. Three daily instillations of a 1 per cent solution for three days, including the day of examination, is usually sufficient. In small children a 0.5 per cent solution is advised, with pressure over the tear sac to avoid systemic symptoms. Dilatation of the pupil for ophthalmoscopic examination is usually obtained with one drop of 2 per cent homatropine hydrobromide. In older persons, 3 per cent euphthalmine, 3 per cent ephedrine sulfate or 1 per cent amphetamine sulfate may be preferred. One drop of 1 per cent pilocarpine after the examination is a wise precaution.

USE OF DRUGS IN GLAUCOMA

The treatment of glaucoma by miotics is based on the fact that stimulation of the sphincter iridis and ciliary body does in many cases reduce intra-ocular tension. The reason for this effect is still debated, but it seems probable that it is due to an opening up of the drainage channels of the anterior chamber. The two miotics most employed are physostigmine (eserine) and pilocarpine. Physostigmine is the more powerful drug and by its prompt effect produces an unpleasant sensation which may amount to real pain. Hence in chronic glaucoma an attempt is usually made to control the tension with a 1 per cent solution or ointment of pilocarpine nitrate. When this does not maintain tension within normal limits, 0.2 per cent physostigmine sulfate or salicylate is tried, instillations being repeated from three to five times a day. Concentration may be increased to 0.4 per cent if miosis is not produced. If the pupils are kept very

1. Gifford, S. R.: *Handbook of Ocular Therapeutics*, Philadelphia, Lea & Febiger, 1937, pp. 95 and 220.
2. Beach, S. J., and McAdams, W. R.: *Am. J. Ophth.* 21: 121 (Feb.) 1938.

small with one of these solutions, however, without reduction of tension to normal, other measures, usually surgical, must be advised. It must be remembered that a very slight increase in tension is enough, in many cases, to produce progressive and irreparable loss of vision. Hence the treatment of chronic glaucoma by miotics is usually unsatisfactory and unsafe unless frequent tests of tension with a standard tonometer and accurate examination of the visual fields can be made. Progressive loss of the visual fields during treatment indicates, as a rule, a prompt resort to surgery, which is usually successful in preserving vision if it is employed in time.

In acute glaucoma, the use of stronger miotics for a brief period is indicated. Instillation of 1 or 2 per cent physostigmine sulfate every ten minutes for one or two hours may abort an attack if employed at the onset. After the attack, weaker solutions are employed. Other measures, such as the intravenous injection of hypertonic solutions, saline catharsis and the use of morphine, are useful adjuncts to the miotics during the first day of acute glaucoma. Slow injection of 100 cc. of 50 per cent dextrose or 200 cc. of 50 per cent sucrose may be of great value. When the tension is not reduced to normal after six or eight hours of such treatment, prompt surgical treatment must usually be advised.

Another group of drugs which may be of value in glaucoma, especially the chronic form, is epinephrine and its derivatives. Epinephrine causes dilatation of the pupil by stimulation of sympathetic nerve endings but also produces marked vasoconstriction of the vascular bed. This effect, in conjunction with the active hyperemia that ensues, results in lowering of intra-ocular tension. This is the case only in eyes with a relatively normal vascular system and hence is of value chiefly in chronic glaucoma. In acute glaucoma, absolute glaucoma and glaucoma secondary to intra-ocular inflammation, lowering of tension is seldom produced and a dangerous rise of tension is, in fact, apt to occur. Even in chronic simple glaucoma the mydriasis must be controlled by preliminary and subsequent use of miotics to avoid such untoward reactions. The chief indication for epinephrine is in cases of chronic glaucoma showing a tension slightly above normal in spite of miotics. Instillation of 1 per cent epinephrine hydrochloride or bitartrate solution several times during an hour, subconjunctival injection of 6 minims (0.4 Gm.) of 1:1,000 epinephrine hydrochloride and insertion of 6 minims of the latter solution on a cotton pledget in the upper conjunctival fold are the methods usually employed. The treatment may be repeated after one or more weeks, but subsequent treatments are often of less value, as is the case with miotics. The danger of such treatment, as of prolonged treatment with miotics, is that overconfidence in their use may result in postponing surgery when it is indicated.

USE OF LOCAL ANESTHETICS

Most local anesthetics³ are absorbed by the conjunctiva and cornea when instilled in the conjunctival sac. Such absorption affords sufficient anesthesia so that minor procedures may be carried out without pain. Such procedures are removal of foreign bodies, testing of intraocular tension, operations for pterygium and suture of conjunctival wounds. In intra-ocular operations, however, operations on the intra-ocular muscles,

curettage of chalazion and removal of the globe, infiltration anesthesia or nerve blocking is essential.

The anesthetic most often employed for instillation and which was first employed therapeutically by the ophthalmologist Koller is cocaine. A 2 per cent solution of the hydrochloride instilled several times will produce effective surface anesthesia in uninfamed eyes. A 4 or 5 per cent solution is often employed preliminary to subconjunctival injections for intra-ocular operations. Cocaine has distinct disadvantages, however. It produces drying of the corneal epithelium, which may result in troublesome corneal erosions unless the eye is kept closed for one or more hours after its use. It also produces mydriasis and, in certain cases, elevation of the intra-ocular tension.

Hence for removal of foreign bodies and for testing intra-ocular tension, one of its substitutes which is without these undesirable properties is advised. Some of these substitutes, with the concentrations usually employed, are butyn sulfate 1 or 2 per cent solution, phenacaine (holocaine) hydrochloride 1 per cent, pontocaine hydrochloride 0.5 per cent and nupercaine hydrochloride 0.2 per cent. The first three drugs are very prompt in their action, while nupercaine is slower but has a more prolonged effect. When a prolonged effect is desired, an ointment of the corresponding strength may be employed.

For infiltration anesthesia or for nerve blocking, procaine hydrochloride is the drug usually employed. It may be used in 4 per cent solution, as the amount usually injected is small.

ANTISEPTICS AND ASTRINGENTS

When an antiseptic is instilled or is used as an ointment in the conjunctival sac, it must be assumed that it comes in contact with the corneal epithelium. This is much more sensitive to pain and more easily damaged than the conjunctival epithelium. Hence the possibility of sterilizing the conjunctival sac by these methods is limited by the tolerance of the corneal epithelium for the drug employed. Other factors to be remembered are the prompt dilution of the drug by the tears and the precipitation of its active constituent by the protein content of the tears or secretion. Any sterile bland solution that is instilled in the conjunctival sac will wash out a certain amount of secretion and débris with any bacteria adherent to them. This is probably the only effect of many antiseptics. The silver proteins, for example, such as mild protein silver, can hardly be supposed to have any other effect, since, according to Sollmann and Pilcher,⁴ even a 100 per cent solution would contain only as much active silver as 0.6 per cent silver nitrate, while the amount in silvol (silver iodide) is even less. A 10 per cent solution of mild protein silver causes no pain or damage to the cornea, while strong protein silver should not be used in concentrations greater than 2 or 3 per cent. Silver nitrate in 0.5 to 1 per cent solutions produces only moderate symptoms of irritation without damage to the cornea. All the protein silvers, as well as silver nitrate, produce permanent staining of the conjunctiva and cornea on prolonged use and hence should never be given to patients with chronic conjunctivitis except for short and definite periods. Too many persons continue using the protein silvers without definite instructions until unsightly staining develops.

Silver nitrate is still the only drug recognized as effective in prophylaxis against ophthalmia neonatorum.

3. Atkinson: *Tr. Am. Ophth. Soc.* 32: 399, 1924. Bellows, J. G.: *Surface Anesthesia in Ophthalmology*, *Arch. Ophth.* 12: 824 (Dec.) 1934.

4. Sollmann, Torald, and Pilcher, J. D.: *J. Lab. & Clin. Med.* 10: 33 (Oct.) 1924.

The use of the 2 per cent solution without neutralization originally employed by Credé produces a rather marked chemical conjunctivitis and has been replaced by either a 1 per cent solution not neutralized or a 2 per cent solution followed after thirty seconds by physiologic solution of sodium chloride. Substitution of the protein silvers or other drugs for prophylaxis has no legal standing and should not be countenanced in hospitals.

The zinc salts are much employed for their astringent and mildly antiseptic effect, a 0.2 per cent zinc chloride or 0.4 per cent zinc sulfate solution being tolerated with only slight local reaction. In conjunctivitis due to the Morax-Axenfeld bacillus, solutions of twice this strength are employed, and in many cases direct applications of a 2 per cent zinc chloride solution to the everted lids after previous anesthesia are required to relieve the infection.

A number of synthetic antiseptics have been prepared which seem to answer the requirements of a conjunctival antiseptic and which seem to be of value, by clinical experience, in the treatment of conjunctivitis.⁵ These include metaphen 1:2,500, mercuraphen 1:2,500, and acriflavine 1:1,500. Mercurochrome is probably less effective but may be used in 1 or 2 per cent solution. Ethylhydrocupreine (optochin) is especially useful in pneumococcal infection. A 1 per cent solution of the hydrochloride is usually employed, although it may cause considerable immediate after-pain. Another use for quinine has recently been described by Selinger,⁶ who applies a saturated solution (1 Gm. to 10 cc. of water) of the bisulfate to the everted lids and prescribes a 2 per cent ointment of the same salt for use by the patient.

Concentrations of other antiseptics which may be instilled without undue irritation are copper sulfate 0.2 to 0.4 per cent, mercury bichloride 1:5,000, mercuric cyanide 1:3,000 and boric acid a saturated solution.

A more prolonged effect of the various antiseptics may be obtained by employing them as ointments. The concentration that is tolerated is about twice that described for the various drugs in solution. Ointments containing antiseptics are of great value in the treatment of blepharitis. Some of the most useful of these are 2 per cent yellow mercuric oxide, 3 per cent ointment of ammoniated mercury and 3 per cent zinc oxide.

A more definite antiseptic effect in conjunctival infection may be obtained by direct application of drugs to the everted lids and folds, the cornea being protected by the other lid. Such treatments require previous anesthetization with 1 per cent butyn or phenacaine hydrochloride and should usually be followed by irrigation with physiologic solution of sodium chloride. Drugs that are applied in this way are silver nitrate from 2 to 4 per cent, zinc chloride 2 per cent, copper sulfate as the crystal or 10 per cent solution, and quinine bisulfate (saturated solution). All these drugs cause a marked to moderate reaction and should be employed with great care, if at all, in the presence of corneal erosions or ulcerations. Antiseptics should be employed only when infection of the conjunctiva can be definitely diagnosed, preferably by smears. Many persons show signs of conjunctival irritation which are not due to infection but to allergic or other chemical irritants or to eyestrain. In such cases the symptoms are only aggravated by the use of antiseptics.

PELLAGRA, BERIBERI AND RIBOFLAVIN DEFICIENCY IN HUMAN BEINGS

DIAGNOSIS AND TREATMENT

CLINICAL LECTURE AT ST. LOUIS SESSION

TOM D. SPIES, M.D.

RICHARD W. VILTER, M.D.

AND

WILLIAM F. ASHE, M.D.

CINCINNATI

During the past ten years, from our studies of deficiency diseases in human beings, we have accumulated evidence which shows that pellagra, beriberi and riboflavin deficiency are clearcut clinical syndromes which frequently coexist and often are associated with other nutritional disorders. This is not surprising, since in natural foodstuffs the water-soluble vitamins are often closely associated and a diet deficient in one chemical substance is almost certain to be deficient in others. In the nutrition clinic at the Hillman Hospital we find that the unbalanced and inadequate diets eaten by the majority of the patients predispose them simultaneously to a number of nutritional disorders and that the diagnosis of one clinical deficiency syndrome necessitates a thorough search for others.

There are thirty-six known constituents of the diet which are essential for adequate nutrition, and it is likely that there are others as yet unknown. Very little significant information has been obtained concerning the body's requirements for certain of these factors, and even less is known of the interrelation of many of these substances in metabolism. However, in spite of the lack of such information, significant clinical studies on the effects of diets deficient in one or more of the known essentials have been carried out. Recently such studies have been facilitated by having available for clinical investigation synthetic nicotinic acid, synthetic thiamin hydrochloride and synthetic riboflavin. The present report is concerned with dietary, clinical and laboratory studies on over 800 consecutive patients with deficiency diseases. We have studied especially the predisposing causes, the development, the early diagnosis and the specific therapy of certain of these deficiency states.

Careful studies of these patients have shown that any single or combined deficiency of the factors essential for good nutrition may arise when there is an inadequate intake, increased need, diminished absorption, increased destruction or diminished utilization of the protective substance or substances. Among our patients the primary cause of the development of these deficiency states was found to be failure to consume a diet quantitatively or qualitatively adequate. This failure, although often due to financial inability to buy proper food, could be attributed in many instances to long-established

faulty dietary habits, food idiosyncrasies, chronic alcoholic addiction resulting in the replacement of food by alcohol, arbitrary diets for relief of gastric symptoms such as dyspepsia and long adherence to unbalanced diets prescribed by physicians for the treatment of diseases such as peptic ulcer, chronic nephritis, chronic colitis, cardiac disease or diabetes mellitus.

It is a common observation that persons with one deficiency syndrome are prone to have associated deficiency diseases. Pellagrins whose psychoses and alimentary disturbances have been treated successfully with nicotinic acid often have lesions of beriberi, riboflavin deficiency, scurvy or vitamin A deficiency. In these patients the therapeutic effect of thiamin hydrochloride, riboflavin, ascorbic acid and vitamin A on beriberi, riboflavin deficiency, scurvy and vitamin A deficiency, respectively, is clearcut and spectacular. The administration of any one of these therapeutic agents is followed by prompt improvement in the lesions diagnostic of the syndrome for which the agent is specific,

weight and strength. Indigestion and dyspepsia are almost universal, and there frequently is some vague type of burning sensation in the epigastrium which most of the patients refer to as "heartburn." The majority of the patients are constipated or have attacks of diarrhea and abdominal cramps. Many describe vague burning, itching and crawling sensations over the skin. They state that they are "nervous," that their "nerves are on edge" and that they are irritable, apprehensive, depressed and unable to sleep. Crying spells, flights of ideas, distractibility, mild mental confusion and forgetfulness are common complaints.² When patients with such symptoms are found to have subsisted for a prolonged period on a deficient diet—whether because of financial inability to purchase food, personal likes and dislikes, faulty assimilation or increased requirement—the prodromal symptoms of a deficiency disease should be considered. Numerically, these patients are much more important than those with classic pellagra and constitute a major economic bur-

but not by improvement of the lesions of associated syndromes so long as the diet of the patient remains constant. Evidence that the background for such multiple deficiency states exists in the diets of typical pellagrins has been shown through complete analyses of the food ingested. These analyses were made by Miss Jean M. Grant of the University of Cincinnati, who found that such diets are deficient in many of the essential nutrients. A typical diet is analyzed in the accompanying table.

The fact that the patients in this series almost constantly eat this type of diet is in direct support of our clinical impression that these patients have multiple nutritional deficiencies. In the endemic areas, the clinical and dietary evidence of deficiencies of nicotinic acid, thiamin and riboflavin is most spectacular, although chronic lack of protein, vitamin A, vitamin C, iron, phosphorus and calcium also is striking.

SUBCLINICAL DEFICIENCY STATES

Persons with early or subclinical deficiencies of the water-soluble vitamins have frequently been described as neurasthenic. Their complaints are extremely numerous and vague and limited to no particular portion of the body. Their appetite is poor, and they have lost

den on society. Since they are unable to support themselves and their families, they must depend on others for their needs. Untreated, these subclinical symptoms may go on for months or years, waxing or waning with the changing seasons, or they may develop rapidly into one or more classic syndromes if the cause of the deficiency is not corrected before infection or some other precipitating factor causes the recognizable manifestations of the disease to appear.

One hundred ninety-nine persons with subclinical deficiencies were divided arbitrarily into groups and given sodium bicarbonate, acetylsalicylic acid or nico-

1. Footnote deleted on proof.

2. It was pointed out last year by Drs. T. D. Spies, W. B. Bean and R. E. Stone (The Treatment of Subclinical and Classic Pellagra, J. A. M. A. 111: 584 [Aug. 13] 1938) that some persons with mental retardation amounting to stupor and without clinical evidence of pellagra often are relieved of their symptoms by the administration of nicotinic acid. Dr. V. P. Sydenstricker, in a personal communication, stated that he has made similar observations. Certain persons with borderline deficiency states frequently develop the full-blown clinical syndrome of the deficiency after the administration of large amounts of carbohydrate. We recommend that undernourished persons receiving injections of dextrose should also receive supplements of the water-soluble vitamins. J. P. Frostig and T. D. Spies will publish within a short time evidence which shows that sixty consecutive patients with subjective symptoms arising from deficiency develop uniform symptoms which have no connection with personality. The initial nervous symptoms have been shown to respond, under controlled conditions, to the administration of large amounts of vitamin B₁ or nicotinic acid. These observations indicate that such deficiency not only cause a decrease in strength but also produce a breakdown in morale.

tinic acid. This study³ was carried out as a therapeutic test in order to distinguish the real from the imagined benefits reported by patients treated with nicotinic acid, since all these drugs in tablet form resemble each other. The patients who received nicotinic acid reported prompt symptomatic relief of their symptoms. The appetite returned and constipation, diarrhea and many of the abdominal symptoms disappeared. The burning sensations over the skin were often relieved; nervousness, headaches and malaise abated, and the patients were able to sleep normally once more. In contrast, the patients receiving acetylsalicylic acid or sodium bicarbonate, although they experienced slight relief during the first few days, soon were consistent in their reports of no symptomatic improvement. The medication was changed without the patients' knowledge to nicotinic acid, and they reported immediate relief of symptoms which was similar to that reported by the patients first treated with this drug. Such improvement, however, occurred only in patients in whom the neurotic manifestations were associated with a diet deficient in foods containing nicotinic acid. Unpublished observations of one of us (T. D. S.) show that many of this group of 199 patients gained sufficient strength to enable them to return to work. Those who obtained positions could afford a better dietary.

Pellagrins in whom the development of the clinical disease is prevented by the administration of nicotinic acid are not relieved of the symptoms of beriberi, riboflavin deficiency, scurvy, vitamin A deficiency or anemia if they continue to ingest their usual inadequate diets. In fact these associated deficiencies often become worse, since the diet is deficient in the specific chemical substances which protect against these diseases.

Studies in the nutrition clinic at the Hillman Hospital from the fall of 1938 to May 15, 1939, show that the administration of vitamin B₁ as a supplement to the usual diet tends to delay, retard or prevent the symptoms of beriberi but not those of pellagra, riboflavin deficiency and other deficiency states. Likewise the administration of riboflavin as the only supplement to the diet tends to prevent, retard or delay the development of symptoms characteristic of riboflavin deficiency but does not prevent the appearance of lesions diagnostic of beriberi, pellagra, vitamin A deficiency, anemia and scurvy. In other words, these substances are specific for their clinical syndrome. Patients receiving supplements of nicotinic acid, vitamin B₁ and riboflavin have uniformly improved more rapidly than have similar groups receiving only one of these substances and, in every instance, have been in better health than the controls subsisting on their usual diets.

Although pellagra, beriberi and riboflavin deficiency occur frequently in the same person, for the sake of ease in description, the diagnosis and treatment of these clinical syndromes will be described independently.

PELLAGRA

Classic pellagra is a syndrome affecting the skin, the alimentary tract and the central nervous system.⁴ It is a disease attacking all strata of society, all races and both sexes.⁵ The diagnosis of pellagra is a clinical one

and is made by observing characteristic glossitis, characteristic dermatitis or both. The affected skin is roughened, erythematous, desquamating, cracked and sharply demarcated from the healthy skin. The lesions are bilaterally symmetric and appear most frequently on the dorsum of the hand, the elbows, knees, ankles, neck and axilla and in the perineal region. They are progressive and constantly changing, so that their appearance varies from time to time. The older the lesion, the more highly pigmented it is likely to be.

The lesions of the alimentary tract usually are the first to appear. The anorexia, burning of the tongue and abdominal pain of the prodromal period gradually give way to intense glossitis, stomatitis, gingivitis, pharyngitis, gastritis and enteritis. The lips are reddened and cracked, and the tongue becomes fiery red, swollen and smooth except where it is indented by the pressure of the teeth. The gums are red and ulcerated, and the pharynx may have the same appearance. Vincent's angina is often superimposed on this devitalized tissue. Gastroscopic examination by Dr. Leon Schiff and Dr. Richard Stevens of the University of Cincinnati College of Medicine revealed fiery red ulcerating lesions of the mucous membrane similar to those found in the mouth. Gastric analysis on such patients shows achylia in 60 per cent of the cases. The enteritis and proctitis result in a foul, watery diarrhea, severe abdominal pain and distention.

The mucous membranes of the genito-urinary tract frequently are affected in a similar manner and are secondarily infected. Severe vaginitis, urethritis and endocervicitis are common. The urethra may be so swollen and injected that a diagnosis of gonorrheal urethritis is made. Vincent's organisms grow in myriads wherever the mucous membranes are affected by pellagra.

Manifestations referable to the central nervous system are common in classic pellagra.⁶ In the late stages they often are of a paranoid type and are accompanied by visual hallucinations, delusions of persecution, depression and reclusiveness. Patients with such manifestations become maniacal and are a source of danger to relatives or attendants. Delirium may develop. Such mental symptoms are evidence of an advanced stage of the disease and require immediate therapy. The administration of nicotinic acid in adequate doses is followed by striking improvement within twenty-four to forty-eight hours. The patient has insight and becomes quiet and cooperative and all evidence of mental disease disappears. Should the mental symptoms persist untreated for weeks or months, a longer period is required for improvement with adequate nicotinic acid therapy and a complete return to normal may never take place. If the condition is untreated, there may develop tremor or rigidity of the extremities, stupor and finally circulatory collapse. In the usual case the mental symptoms arise first from the cortex, and as the disease becomes more severe from the mid-brain, and finally from the bulbar region.

BERIBERI

Thiamin deficiency, or beriberi, most commonly manifests itself as polyneuritis and frequently is associated with pellagra. The prodromal period of beriberi, like that of pellagra, is characterized by vague complaints referable to many systems of the body, although at this stage no objective signs can be elicited. There is a loss

4. Spies, T. D.; Cooper, Clark, and Blankenhorn, M. A.: The Diagnosis of Pellagra, *Internat. Clin.* 4: 1 (Dec.) 1937.

5. Unpublished observations made in collaboration with Miss Jean M. Grant show that pellagra in many of these persons actually begins early in childhood. We have observed that in a number of children in "pellagra families," who were free from pellagra several years ago, early lesions of the disease are now developing. During the past year, 206 children with pellagra, forty with beriberi and twenty with riboflavin deficiency have responded to specific therapy.

6. Spies, T. D.; Bean, W. B., and Ashe, W. F.: Recent Advances in the Treatment of Pellagra and Associated Deficiencies, *Ann. Int. Med.* 12: 1830 (May) 1939.

of appetite, weight and strength. The patient may complain of muscular cramps, diarrhea, palpitation and shortness of breath. Burning, numbness and tingling of the extremities are more specific and forewarn of a developing peripheral neuritis. Should vitamin B₁ deprivation continue, all symptoms become more pronounced and group themselves under the alimentary, peripheral nervous and cardiovascular systems.⁷

The pathologic changes in the alimentary tract, although not well understood, produce altered motility, which results in anorexia, nausea, vomiting, diarrhea or constipation. Pathologic changes in the peripheral nervous system result in myelin degeneration of the peripheral nerves, which leads to the signs and symptoms of peripheral neuritis. Patients in whom these myelin changes have occurred complain that the soles of their feet burn like fire and that their hands tingle and are numb. There are tenderness over the nerve trunks and over the calves of the legs and muscular weakness and degeneration, especially in the tibialis anticus and peroneal groups of muscles. In the early stages the tendon reflexes are hyperactive; later, however, they are diminished or absent. Changes in the upper extremities usually appear only after similar changes in the lower extremities have become very severe. Sphincter tone is usually unimpaired.

The clinical syndrome just described is the so-called dry beriberi. Less frequently, thiamin deficiency manifests itself also as wet beriberi, with the formation of edema and serous effusions. The cause of the edema is debatable; it may be due to changes in the heart, the peripheral vascular system or the intercellular and intracellular fluids themselves. The edema begins in the lower extremities and gradually extends upward. With it may be associated hydrothorax, ascites and pericardial effusion. The wet type is acute more frequently than chronic. The acute variety, seen more frequently in children than in adults, is characterized by rapid onset, lack of prodromal symptoms, dyspnea, edema, tachycardia, precordial pain, increased venous pressure, cardiac murmurs and a small thready pulse. Typical electrocardiographic changes have been described.⁸ The patient may go into shock and die suddenly.

From the foregoing observations it will be seen that a diagnosis of beriberi requires that the patient have evidence of peripheral neuritis with or without edema, cardiovascular or gastrointestinal abnormalities and a history of a diet deficient in vitamin B₁. This deficiency may be due to indigence, loss of appetite secondary to other debilitating diseases, failure of assimilation or an increased requirement due to thyrotoxicosis, pregnancy, lactation or rapid growth. Since there are no adequate clinical tests for thiamin deficiency other than the therapeutic test, the diagnosis can receive little help from the laboratory. However, as with all other deficiency diseases, success in treatment depends on accuracy in diagnosis.

DEFICIENCY SYNDROME RESPONDING TO RIBOFLAVIN

There is a deficiency syndrome which responds to the administration of riboflavin, the characteristics of which are not as yet completely differentiated from the

signs and symptoms of related deficiencies. Sebrell and Butler⁹ have described cracking at the corners of the mouth with erosion of the mucous membranes in experimental subjects. They have reported that this lesion responds only to the administration of riboflavin. We have observed similar lesions occurring naturally in forty patients and have had similar success in treatment with riboflavin.¹⁰ We have observed also in many of these patients a roughening of the skin around the mouth and across the tip of the nose, which has the appearance of "sharkskin." The pores of the affected areas are filled with sebaceous material. These cutaneous changes also respond to riboflavin therapy. The disease is unusually common in undernourished women toward the end of pregnancy.

A lesion of the eyes¹¹ characterized by bulbar conjunctivitis, lacrimation, burning of the eyes and failing vision has responded in some instances after the same treatment. It is too early to interpret these observations, since in other cases similar lesions respond to large doses of carotene.

Just as subclinical pellagra and subclinical beriberi are much more common than the classic types, so are subclinical cases of riboflavin deficiency more numerous than the typical ones.

The development, symptoms, methods of study and mode of treatment in a representative case of nutritional deficiency are presented in the following report:

D. D., a white man aged 36, who had been subsisting on the diet shown in the accompanying table, was followed in the pellagra clinic at the Hillman Hospital during the summer of 1938. At that time he showed no definite signs of pellagra but complained of general malaise, anorexia, epigastric distress, constipation, aching in the lower extremities and weakness, which have been described as prodromal symptoms of clinical pellagra and beriberi. He was given no specific therapy and was not seen again until he returned to the clinic March 10, 1939, with the same complaints. He stated that his tongue burned at times as though it had been scalded by hot coffee, that his appetite was poor and that ingested food caused epigastric burning. He was constipated, extremely nervous and unable to sleep and suffered from almost constant headache, dizziness and weakness. He volunteered the information that for more than a year his eyes had felt as though they were full of sand and that recently they had begun to water and burn excessively, especially when he attempted to read or exposed them to wind and cold air. He stated also that his feet were swollen and numb, that the soles of his feet burned and that his legs cramped and ached.

Examination showed a reddened and swollen tongue, cracking and excoriation at the corners of the lips, mild conjunctival capillary dilatation, which was most marked at the inner canthus and extended in a triangular formation to the cornea, and dilated pupils which reacted sluggishly to light. His feet were hyperesthetic to pinprick and light touch, his ankles hypesthetic and his calves extremely tender. All deep reflexes of the lower extremities were hypotonic or absent.

Extractions of the urine with ether and 25 per cent hydrochloric acid brought out the purple color and spectral absorption bands of porphyrin (coproporphyrin I and III) and porphyrin-

11. We have observed what appear to be undescribed manifestations of a deficiency state. More than 70 per cent of the patients in the nutrition clinic who have frequent recurrences of pellagra, beriberi or flavin deficiency also have visual disturbances. Some of these symptoms are characteristic of vitamin A deficiency. Many patients are unable to see well, have dry burning of the eyes and, on examination, show marked conjunctivitis, particularly in the conjunctiva of the lower lid. Also, the pupils of a great majority of persons in the clinic, including children, are greatly dilated.

8. Weiss, S., and Wilkins, R. W.: The Nature of the Cardiovascular Disturbances in Nutritional Deficiency States (Beriberi), *Ann. Int. Med.* 11: 104 (July) 1937.

like substances.¹² Analyses of the same specimens of urine by the dinitrochlorobenzene method¹³ resulted in very low values for the output of nicotinic acid. Similar low results were obtained for the codehydrogenase content of both blood and urine by the method¹⁰ based on the growth requirements of the influenza bacillus.

The patient was treated at this time with nicotinic acid,¹⁴ given orally in amounts of 100 mg. daily for twelve days. Because of the poor clinical response, the dose was increased to 500 mg. daily for four days. At the end of this period, the patient reported that he felt stronger than he had at any time during the preceding year, that he had no complaints referable to the alimentary tract, and that his nervousness and dizziness had been relieved. The increased "porphyrinuria" disappeared, and the concentration of co-enzyme (codehydrogenase) in both the blood and the urine increased to within normal limits. The symptoms referable to the eyes and to the peripheral nervous system, however, became worse during the next week.

Because of the well known relationship between vitamin A deficiency and such ocular manifestations as xerophthalmia and night blindness, carotene in oil (vitamin A)¹⁴ was administered to this patient in doses of 100,000 units daily for five days. Relief of the ocular symptoms followed. Similarly, two weeks later the cracked, dry, scaling lesions (cheilosis) at the corners of the patient's mouth responded to the administration of 50 mg. of riboflavin¹⁵ given orally each day for three days. Healing of the lesions began on the second day and was completed six days after riboflavin was first administered. Urinary flavin determinations¹⁶ before therapy showed marked reduction in the output of this substance and a rapid rise to values higher than normal after the administration of riboflavin. There was no appreciable change in blood cozymase during this period.

The patient continued to complain, however, of the burning, tingling and numbness of his feet and legs. He was given repeated injections of sterile physiologic solution of sodium chloride, and the symptoms became so severe that codeine no longer would dull the pain enough for him to sleep. We had shown previously that patients with beriberi fail to respond to repeated injections of sterile physiologic solution of sodium chloride but do respond to the intravenous administration of from 15 to 20 mg. of vitamin B₁ twice a day for two or three

days. Since we¹⁷ had shown that cocarboxylase (the co-enzyme of vitamin B₁) acts in a manner similar to vitamin B₁, we made the following test: Ten milligrams of cocarboxylase (pyrophosphorylated thiamin)¹⁸ was injected twice daily for three days. After the first twenty-four hours the patient noted less pain and stiffness in his legs and after seventy-two hours all sensory symptoms had been alleviated, although little change other than increased strength was noted in repeated neurologic examinations. The patient is now at work and volunteers that he feels much stronger and better able to work than at any time during the past three years.

This case illustrates the extremely important concept that nutritional deficiencies exist as complexities and not as single entities. The controlled studies on this patient show that he had four distinct deficiency diseases. The pellagra responded to the administration of nicotinic acid, the beriberi to vitamin B₁ (cocarboxylase), the riboflavin deficiency to the administration of riboflavin and the vitamin A deficiency to the administration of carotene in oil (vitamin A). Recently we have seen typical scurvy develop in clinic patients who had been treated adequately with nicotinic acid for pellagra and with vitamin B₁ for beriberi. The hypochromic anemia of iron deficiency is almost universal, especially among the women of the nutrition clinic.

GENERAL PRINCIPLES OF THERAPY

The more accurate the initial diagnosis of pellagra, beriberi, riboflavin deficiency, anemia, scurvy, vitamin A deficiency, or combinations of these deficiency states, the more likely is the physician to avoid futile treatment with unnecessary preparations. In the treatment of any one or several of these deficiency syndromes, the problem is one of administering adequate amounts of the deficient substance or substances in a way in which it or they can be utilized. Whether for the adult or the infant, therapy should be directed along three lines: 1. There should be elimination of any conditions causing excess requirement of the specific substances. 2. There should be administration of the lacking substance or substances in amounts adequate to correct the deficiency. 3. There should be symptomatic treatment and treatment for coexisting diseases. Each patient should be treated individually, and the indications for treatment depend on the clinical information available to the physician.

Since the minimal, maximal and optimal doses of the specific therapeutic agents are not known, no routine of treatment can be satisfactorily followed. Each patient ill enough to warrant hospitalization should be considered as an emergency. If possible, such patients should remain in bed and should be given frequent attention by the physician, nurse and dietitian. The essence of treatment consists in the administration of adequate amounts of foods rich in the missing materials, supplemented if possible by the administration of large amounts of specific therapeutic agents. The foods included in the dietary depend of course on the age, race, habits, tastes and financial status of the patient. A well rounded diet of 4,500 calories, rich in meat, liver, eggs and milk, should be given as a routine. When the prescribed diet cannot be followed, from 75 to 100 Gm. of dry brewers' yeast¹⁹ daily is a valuable supplement.

12. The majority of patients with subclinical pellagra and of pellagrins in relapse before diagnostic clinical signs appear excrete in the urine increased amounts of an ether-soluble substance or substances which give the color of porphyrin in 25 per cent hydrochloric acid. The prompt disappearance of these substances from the urine following the administration of large amounts of nicotinic acid can be used as an early objective test. It should be emphasized that coproporphyrin III is only one of the abnormal pigments found in the urine. The nature of the other substances is unknown, but it is probable that they are related to bile pigments. The abnormal pigments disappear as the pellagrin responds to adequate therapy. The test is simple and easy to perform. Urine is acidified with glacial acetic acid and extracted with ether, and the ether is washed with water and finally extracted with 25 per cent hydrochloric acid. The color appears in the acid layer. A complete report of this method, together with its limitations, has been published:

14. The nicotinic acid in the prevention study was furnished jointly by the S. M. A. Corporation, Chicago, and John Wyeth & Brother, Inc., Philadelphia, and the carotene in oil used in this study was supplied by the former corporation.

15. The riboflavin and cocarboxylase were furnished through the courtesy of Drs. J. M. Carlisle, Hans Molitor and Randolph Major of Merck & Co., Rahway, N. J.

16. A modification of Emmerie's method (Emmerie, A.: Determination and Excretion of Flavins in Normal Human Urine, *Nature* 138: 164 [July 25] 1936) for the determination of the flavin shows that persons who acquire riboflavin deficiency excrete less riboflavin in the urine than do normal persons. Application of these methods to persons with characteristic riboflavin deficiency shows that at the time the lesions are at their height the excretion of riboflavin in the urine is somewhat less than normal. The administration of riboflavin is quickly followed by excretion of this substance in the urine.

SPECIFIC TREATMENT FOR PELLAGRA

Nicotinic acid, nicotinic acid amide and sodium nicotinate are effective in the treatment of pellagra. They may be administered orally in tablet or capsule form or parenterally in physiologic solution of sodium chloride. Unless the powers of absorption are greatly impaired, oral administration is preferred. Opinion with regard to dosage differs. Although the optimal dosage probably varies considerably for different pellagrins, experience with a large series has shown that 500 mg. of nicotinic acid¹⁹ administered daily in 50 mg. doses is safe and effective for the average patient with pellagra. We have observed that only 50 mg. daily may be required for mild pellagra but that in rare instances as much as 1,000 mg. daily may be required for very severe pellagra. Administered parenterally, the total daily dose varies from 40 to 80 mg., dissolved in sterile physiologic solution of sodium chloride and injected intravenously in divided doses of from 10 to 15 cc. each. The dose of nicotinic acid amide and sodium nicotinate is similar to that of nicotinic acid. The oral administration of ten doses of 50 mg. each at hourly intervals is more effective than administration of a single dose of 500 mg. This suggests that the controlling factor is the concentration of compounds of nicotinic acid in the blood and tissues.

SPECIFIC TREATMENT FOR BERIBERI

Infantile beriberi is treated best by giving, intramuscularly or intravenously, 5 mg. of thiamin hydrochloride in sterile physiologic solution of sodium chloride twice a day. Ten milligrams of the same substance may be given by mouth each day. Satisfactory antiberiberic treatment of the mother will aid greatly in the treatment of the nursing child.

For the adult, from 20 to 50 mg. should be given daily for severe beriberi. From 5 to 10 mg. a day is adequate for the mild form. Parenteral injections, irrespective of the patient's age or any other condition, are always indicated when vitamin B₁ deficiency is associated with severe cardiac failure, severe peripheral neuritis or severe alimentary disturbances. There is no question but that the oral administration of thiamin in adequate doses proves efficacious in the average case. However, patients are encountered who are refractive to oral medication. The advantages of parenteral therapy over oral treatment include the following: 1. Parenteral administration causes more rapid improvement in the patient. 2. There is the certainty that the patient will actually absorb it. A deranged gastrointestinal tract cannot serve as a block to absorption. 3. Massive doses of the active substance can be given more easily. 4. The management of the patient is so arranged that the medication is given under the supervision of the physician, thus eliminating carelessness or other possible interferences.

SPECIFIC TREATMENT FOR RIBOFLAVIN DEFICIENCY

Riboflavin deficiency responds to the oral administration of riboflavin more slowly than does pellagra to the oral administration of nicotinic acid. We have concluded tentatively that a dose of 5 mg. a day given orally will heal lesions at the corners of the lips within four to six days and that when administration of the drug is discontinued, if the diet and the state of health remain unchanged, there may be a recurrence within

eight to twenty days. Furthermore, it can be reported with certainty that in many cases the administration of riboflavin increases the efficiency of nicotinic acid in the treatment of certain pellagrins. Three pellagrins had a relapse when treated with 1,000 mg. of nicotinic acid a day but improved once more when riboflavin was added to the existing therapy. On the basis of this data, we have concluded that certain pellagrins benefit from the addition to their medication of riboflavin in daily doses of 5 mg. given orally even if no specific evidence of riboflavin deficiency can be found.

The administration of from 50 to 75 Gm. of dry brewers' yeast is followed by rapid improvement in the patient's general condition and by disappearance of the lesions characteristic of riboflavin deficiency. Likewise, a well balanced diet administered over a period of two days is adequate and causes a similar spectacular response.

SUMMARY AND COMMENT

Specific therapy with synthetic chemical substances will, when administered to patients with specific deficiency diseases, bring about a remission of the symptoms and signs characteristic of these diseases, even when the patient is maintained on a diet of dextrose and distilled water. Thus it has been demonstrated that nicotinic acid will bring about a remission of pellagra, thiamin will remit beriberi and riboflavin will heal the lesions of riboflavin deficiency. However, adequate medical care of patients with such deficiencies does not consist of specific therapy alone. Improvement will be much more striking and permanent if these patients are maintained on a well balanced and liberal diet, at least one half of which should consist of lean meat, milk and eggs. Full details of these dietary principles have been published.²⁰ When it is impossible for the patient to obtain this type of diet, 75 Gm. of brewers' yeast, 100 Gm. of rice polishings (tikitiki) or 150 Gm. of wheat germ daily is extremely valuable as a daily supplement to the diet.

The patient with severe pellagra or beriberi with cardiovascular manifestations requires complete rest in bed and adequate nursing care. It is of the utmost importance that the medication be given regularly and that he be helped and encouraged to eat the prescribed diet. Should the patient be so uncooperative that he refuses solid food, a liquid diet of from 4,000 to 4,500 calories may be given in frequent small feedings by gastric gavage.

The importance of a well balanced diet is further emphasized by the observations that pellagrins treated with nicotinic acid and without a change in their dietary regimen often acquire beriberi, riboflavin deficiency or both after the manifestations of pellagra have been relieved. These manifestations do not occur when the patient eats a balanced diet. In the nutrition clinic at the Hillman Hospital it has been impossible to alter appreciably the habits of patients who have been conditioned by economic necessity to subsistence on diets deficient in many essential nutrients. In such cases, after treatment the diet has been supplemented with nicotinic acid, 50 mg. ten times a day; thiamin hydrochloride, 10 mg. twice a day, and riboflavin, 5 mg. once a day. Since the medication is absorbed much more slowly and evenly when given orally, this method of administration is preferred for patients who are not severely ill. After such a regimen, should other

19. The synthetic nicotinic acid used in this study was supplied by Merck & Co., Rahway, N. J.; Harris Laboratories, Tuckahoe, N. Y.; Abbott Laboratories, North Chicago, Ill.; Mead Johnson & Co., Evansville, Ind., and S. M. A. Corporation, Chicago.

20. Spies, T. D.; Chinn, A. B., and McLester, J. B.: Severe Endemic Pellagra: A Clinical Study of Fifty Cases with Special Emphasis on Therapy, J. A. M. A. 108: 853 (March 13) 1937.

deficiency states, such as scurvy, xerophthalmia or hypochromic anemia develop, they may be treated with ascorbic acid, carotene or iron as required.

Studies still in progress indicate that patients who complain only of the symptoms described as the prodromal symptoms of the specific deficiency states report a definite increase in sense of well-being and disappearance of many of their complaints when nicotinic acid, vitamin B₁ and riboflavin are added as supplements to their inadequate diets. Such supplements, varying greatly in amounts for each individual patient, will retard, delay or prevent the development of clinical pellagra, clinical beriberi and clinical flavin deficiency.

These therapeutic agents (nicotinic acid, thiamin hydrochloride and riboflavin) are components of important intracellular enzymes. Nicotinic acid in its amide form is an important constituent of the cozymase of von Euler²¹ and of the coferment of Warburg.²² We have shown¹⁰ that in severe pellagra in relapse the blood levels of codehydrogenases I and II (cozymase and coferment) are below normal and that these coenzymes may be returned to their normal levels in the blood by the administration of nicotinic acid or its amide. Thiamin hydrochloride (vitamin B₁) in its phosphorylated form (cocarboxylase) is another important coenzyme. In the present study it is demonstrated that synthetic cocarboxylase (phosphorylated thiamin) is dramatically effective in the treatment of beriberi. Riboflavin (vitamin B₂) in its phosphorylated form combined with a specific protein is the "yellow enzyme" of Warburg and Christian.²³ We have shown that the phosphoric acid ester of riboflavin is highly effective in clearing up the lesions of riboflavin deficiency.

Since normal intracellular metabolism depends in large part on the close interrelation of many enzymes, we may postulate, as a working hypothesis, that the pathologic physiology of these deficiency states will be better understood when final information is available as to the nature and function of the enzymes.

Nine hundred and seventy-seven consecutive persons who came to the Hillman Hospital, Birmingham, Ala., because of pellagra, beriberi or riboflavin deficiency, were treated, without a single admission to the hospital and without a fatality. From these and previous clinical observations, and from accurate analyses of the diets of pellagrins, we have concluded that multiple deficiency states are very common and that no single chemical substance will serve to control these deficiencies. The case that is reported illustrates both the development of multiple deficiencies in a clinic patient and the method by which these deficiencies are studied, including observations, laboratory methods and therapeutic procedures. We have described the typical symptomatology of pellagra, beriberi and riboflavin deficiency as it is found in this clinic and have indicated the most satisfactory and efficient therapeutic agents in these conditions. Since much has been learned recently concerning the chemical development of these nutritional states, we have discussed the relationship of nicotinic acid to cozymase and coenzyme, of thiamin to cocarboxylase and of riboflavin to the yellow enzyme of Warburg and Christian; and we have emphasized the importance of providing a well balanced diet both for the prevention and for the treatment of these nutritional deficiencies.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT. THE COUNCIL EXPRESSES ITS APPRECIATION TO THE CONSULTANTS ON OPHTHALMOLOGY FOR THEIR COOPERATION IN THE INVESTIGATION OF THESE CHARTS. THE CONSULTANTS ARE DR. SANFORD GIFFORD, CHAIRMAN, DR. FRANCIS H. ADLER, CHARLES A. BARN, S. JUDD BEACH, WILLIAM L. BENEDICT, CONRAD BERENS, ALFRED COWAN, JOHN EVANS, JONAS FRIEDENWALD, WALTER B. LANCASTER, WILLIAM H. LUEDDE AND CLIFFORD WALKER.

HOWARD A. CARTER, Secretary.

BETTS CHARTS NOT ACCEPTABLE

Manufacturer: Keystone View Company, Meadville, Pa.

The purpose of these charts, the manufacturer states, is to provide a simple quick and conclusive means for a nurse, doctor, psychologist, reading supervisor, teacher or principal to test school children: (1) for psychologic maturity before entering school (called Reading Readiness Tests in school language); (2) for visual skill (testing automobile drivers, for example); and (3) for testing so-called oculomotor and perception habits.

The equipment consists of (1) an ophthalmic telebinocular, (2) ten visual sensation and perception slides, (3) five maturation cards and (4) ten oculomotor and perception habit slides.

The ophthalmic telebinocular is a stereoscope based on the Brewster principle. The slides themselves may be used in this instrument or any other good stereoscope with similar optical proportions.

Ten visual sensation and perception slides are photographs, the company writes, designed for testing visual acuity, fusion, coordination, lateral and vertical deviations and the presence or absence of refractive errors. These tests may be taken at infinity and at reading distance.

The five maturation cards, according to the firm, are designed for testing reading readiness.

Ten oculomotor and perception habit slides, the manufacturer states, are designed for the use in psychologic departments to determine whether the tendency to reverse and mix up words may be psychologic, demanding special pedagogic help, or ocular, demanding the ophthalmologist's help.

The instruments and charts were investigated by the consultants and the report submitted to the Council was adopted and sent to the firm in May 1937. In the firm's reply, objection was raised to certain parts of the report and the firm asked for further opportunity to gather evidence and also asked the consultants to investigate the charts further. After about two years the consultants have finished and presented their report. This report considers only the essential question: "Do the charts offer advantages over other methods of testing the eyes of children, such that the Council is justified in accepting them, which implies recommendation that they be used in schools?"

To this question after long consideration by its consultants, the Council is forced to give a negative answer. It has been the experience of the consultants that many children have been referred to them because of unsatisfactory tests with the Betts Charts who showed no anomalies of vision, muscle balance or fusion which would be considered a factor in reading disability. The number of such cases has increased in recent years. The parents have been told, in many cases, that eye defects were in all probability the cause of their children's difficulties in school and it has often been difficult to persuade them that other factors must be responsible. Parents are naturally averse to admitting that defects of mental equipment or attention are at fault and some will accept the school examiner's opinion in preference to that of the ophthalmologist. This is especially true when parents have been told by the school examiner the exact error in muscle balance or refraction revealed by the Betts Charts and this error is not confirmed by the ophthalmologist. It is recognized that this is not done according to the instructions of the manufacturers, but the fact remains that it is often done, and that the charts as employed lend themselves to such misleading diagnosis by school examiners.

This experience by the consultants has received additional support by the results of a recent investigation in a group of schools conducted, in part, at the instigation of the consultants. In this study, as yet unpublished, a large number of children

were tested with the Betts Charts and with a series of tests covering the points of vision, stereopsis and muscle balance, by the methods considered to be most accurate and which may be called the standard methods. Results with the Betts Charts indicated that 75 per cent of the children required attention to the eyes, a figure approximately twice that obtained with the standard series of tests. No satisfactory evidence has been submitted that differences in vision obtained with the two eyes used simultaneously in the stereoscope as compared with that of each eye tested separately or between the vision of children tested for near and distant vision are of any practical importance. In this our consultants differ with the manufacturers, who emphasize this point. In the opinion of the consultants the tests for astigmatism and other refractive errors are not exact and lend themselves to misleading diagnoses.

It is not an essential part of this report, but it may be mentioned that a number of consultants have objected to the sales methods employed in attempting to place the Betts Charts in the schools. No matter how fair the policy of the company, some of the consultants have no doubt that methods to which they feel they can justly object have been employed by agents of the manufacturers.

In conclusion, it is the opinion of our consultants that the results of tests with the Betts Charts applied to school children are misleading by greatly overestimating the number of children in whom ocular anomalies are a factor in reading disability and hence by allowing other equally important factors to be overlooked. It is admitted that any series of tests may be misleading in individual cases, but it is the opinion of our consultants that this objection applies in the case of the Betts Charts to so large a number of observations that they cannot recommend acceptance of the material submitted.

In view of the report of the Consultants on Ophthalmology, the Council on Physical Therapy voted not to include the Betts Charts (Keystone View Company) in its list of accepted devices.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

PROTEIN EXTRACTS-ARLCO.—Liquids obtained by extracting the protein of substances believed to be the cause of specific sensitization.

Actions and Uses.—See Allergic Protein Preparations, New and Nonofficial Remedies, 1939, page 27.

Dosage.—See Allergic Protein Preparations, New and Nonofficial Remedies, 1939, page 27.

Protein extracts-Arlco are marketed in packages of four 5 cc. vials, one each of four concentrations. In the case of food and incidental extracts these are 1:10,000, 1:5,000, 1:1,000 and 1:500. In the case of animal epidermal and fur protein extracts the concentrations are 1:100,000, 1:10,000, 1:1,000 and 1:500. Concentrations of 1:500 and 1:100 and occasionally intermediate dilutions are also marketed in 1, 2, 3, 5 and 10 cc. vials.

Manufactured by The Arlington Chemical Co., Yonkers, New York. No U. S. patent or trademark.

Protein extracts-Arco, with two exceptions (Egg White and Wheat, Whole), are prepared as follows: A weighed amount of the dried protein material, prepared as indicated in this description, is suspended in twentieth-normal sodium hydroxide solution. The suspension is centrifuged and decanted and the residue, if one remains, exhausted by successive extractions with twentieth-normal sodium hydroxide solution. The extracts are combined and filtered until clear. To the filtrate is added one-fourth volume of a solution containing in each hundred cubic centimeters sodium phosphate ($\text{Na}_2\text{HPO}_4 \cdot 12\text{H}_2\text{O}$) 1.43 Gm. and potassium dihydrogen phosphate (KH_2PO_4) 0.363 Gm. The reaction of the resultant solution is then adjusted to pH 8.3 by the addition of either hydrochloric acid or sodium hydroxide solution. Cresol in the proportion of 0.4 per cent is added and the solution sterilized by filtration through Berkefeld filters. The finished products are tested for sterility according to the methods required by the U. S. Public Health Service. The protein content of the sterile solution is estimated by multiplying the nitrogen content, determined according to the Kjeldahl method, by the factor 6.25; dilutions are made on the basis of the estimated protein content.

The dried protein material used in the preparation of the extracts marked 1 is prepared as follows: The hard shells are removed; nuts are ground and extracted with carbon tetrachloride or acetone to remove oils. The residue is extracted with tenth-normal sodium hydroxide solution. The extract is neutralized with tenth-normal sodium hydroxide and the resulting precipitate collected, dried and sifted.

The dried protein material used in the preparation of the extracts marked 2 is prepared as follows: The edible portion is separated from the nonedible parts (scales, bones and so on) and finely ground. The extract is then extracted with tenth-normal sodium hydroxide solution. The extract is neutralized with tenth-normal sodium hydroxide solution. The precipitate collected, dried and sifted.

The dried protein material used in the preparation of the extracts marked 3 is prepared as follows: The material is washed in acetone and ether and then ground and sifted.

The dried protein material used in the preparation of the extracts marked 4 is prepared as follows: The seeds are separated and the material chopped fine. An extract is made, sufficient tenth-normal sodium hydroxide solution being used to make the mixture alkaline to litmus. The extract is filtered and neutralized and the resulting precipitate collected, dried and sifted.

The dried protein material used in the preparation of the extracts marked 5 is prepared as follows: The material is chopped and after mixing with thymol is spread on trays to dry. The dried material is then extracted with tenth-normal sodium hydroxide solution. The extract is neutralized with tenth-normal sodium hydroxide solution. The precipitate collected, dried and sifted.

The dried protein material used in the preparation of the extracts marked 6 is prepared as follows: Whites of eggs are mixed thoroughly with two volumes of distilled water, heated to 80 C. and made faintly acid. The precipitate is filtered off and discarded. To the filtrate are added two and one-half volumes of acetone. The precipitate formed is collected, dried and sifted.

The dried protein material used in the preparation of the extracts marked 7 is prepared as follows: Egg yolks are thoroughly mixed and washed in acetone and ether to remove fat. The residue is extracted with 10 per cent sodium chloride solution. The extract is filtered off and placed in a dialyzer. The precipitate is collected, washed in distilled water, dried and sifted.

The dried protein material used in the preparation of the extracts marked 8 is prepared as follows: Skimmed milk is diluted with two volumes of distilled water. Diluted hydrochloric acid is added until the casein settles out. The casein is filtered off and added until saturated and concentrated in vacuo. Ammonium sulfate is added to saturation point and the precipitate redissolved in distilled water. The solution is placed in a dialyzer and allowed to remain until the sulfate test is negative. The lactalbumin, precipitated by the addition of two and one-half volumes of acetone, is collected, dried and sifted.

The dried protein material used in the preparation of the extracts marked 9 is prepared as follows: The five protein fractions present in the protein precipitated with acetone, are dissolved in or acetone, dried, ground and sifted.

The dried protein material used in the preparation of the extracts marked 10 is prepared as follows: The protein is washed with in and separately prepared from wheat flour are mixed.

The dried protein material used in the preparation of the extracts marked 11 is prepared as follows: Wheat flour is extracted with distilled water. The extract is collected, filtered clear and made slightly acid. It is then heated to 65 C. and the precipitate filtered off, dried and sifted.

The dried protein material used in the preparation of the extracts marked 12 is prepared as follows: The filtrate obtained after removing

wheat leucosin is concentrated in vacuo. Four volumes of acetone are added and the resulting precipitate separated, dried, ground and sifted. The dried protein material used in the preparation of the extract marked 13 is prepared as follows: Wheat flour is extracted with distilled water to remove the leucosin and protease; the residue remaining is then extracted with 10 per cent sodium chloride solution. The precipitate is washed with water, dried and sifted.

The dried protein material used in the preparation of the extract marked 14 is prepared as follows: The residue of wheat flour remaining after the flour has been extracted with water and with 10 per cent sodium chloride solution is extracted with 80 per cent alcohol. The extract is concentrated in vacuo, dried, ground and sifted.

The dried protein material used in the preparation of the extract marked 15 is prepared as follows: Wheat flour is extracted with tenth-normal sodium hydroxide solution and then extracted with 80 per cent alcohol. The residue remaining is then extracted with tenth-normal sodium hydroxide solution. The extract is neutralized with tenth-normal sodium hydroxide and the precipitate collected, dried and sifted.

The dried protein material used in the preparation of the extracts marked 16 is prepared as follows: The material is extracted with tenth-normal sodium hydroxide solution. The extract is neutralized with tenth-normal sodium hydroxide and the precipitate collected, dried and sifted.

The dried protein material used in the preparation of the extract marked 17 is prepared as follows: The material is extracted with tenth-normal sodium hydroxide solution. The extract is neutralized with tenth-normal sodium hydroxide and the precipitate collected, dried and sifted.

The dried protein material used in the preparation of the extract marked 18 is prepared as follows: Equal parts of the egg white and egg yolk proteins are mixed.

The dried protein material used in the preparation of the extract marked 19 is prepared as follows: Fresh skimmed milk is diluted with two volumes of distilled water. Diluted hydrochloric acid is added until the casein separates out. The casein is redissolved in sodium hydroxide solution and reprecipitated with diluted hydrochloric acid. It is then washed, dried, ground and sifted.

The dried protein material used in the preparation of the extracts marked 20 is prepared as follows: After removal of feathers, bones, and the like, any excess fat is trimmed off. The meat is collected and chopped fine. The material is then extracted with tenth-normal sodium hydroxide solution. The extract is neutralized with tenth-normal sodium hydroxide and the resulting precipitate collected, dried and sifted.

The dried protein material used in the preparation of the extracts marked 21 is prepared as follows: The material is chopped thoroughly or reduced to a fine powder by grinding. Where excess oil or fat is present, this is removed by treatment with acetone or carbon tetrachloride. The material is then extracted with tenth-normal sodium hydroxide solution. The extract is then neutralized with tenth-normal sodium hydroxide and the resulting precipitate collected, dried and sifted.

The extracts marked 22 are prepared by the same method used in the preparation of pollen extracts-Arco (q. v.).

Exceptions to the general method of preparation: 1. Egg white protein from the yolks. The egg whites are added to an equal volume of physiologic solution of sodium chloride, passed several times through cheese cloth, and sufficient saline and "phosphate solution" (having the composition previously stated in this description) added to bring the protein content to about 1:100 (calculated). The solution is then adjusted to pH 8.3; cresol is added and the solution sterilized by Berkefeld filtration. From this point the procedure follows the general method outlined in the beginning of this description.

2. Wheat (whole) protein extract-Arco: Part I: Wheat flour is extracted with 10 per cent sodium chloride solution, chloroform being used as a preservative. The extract is filtered off and dialyzed against running water until freed from salt, toluene and chloroform being used as preservatives. The solution is then centrifuged and the supernatant fraction reduced in volume in vacuo. The precipitate from dialysis is dissolved in twentieth-normal sodium hydroxide solution, filtered and combined with the reduced supernatant fraction. One-fourth volume of "phosphate solution" (of the composition already described) is added to the reaction of the solution adjusted to pH 8.3, and the solution filtered by Berkefeld filtration. The protein content is estimated by a nitrogen determination ($\text{N} \times 6.25$). Part II: An appropriate amount of wheat flour is freed from starch, the residue dissolved in tenth-normal sodium hydroxide solution, the solution filtered until clear, and its reaction adjusted to pH 8.3. Cresol 0.4 per cent is added and the solution sterilized by Berkefeld filtration. The protein content is estimated by a nitrogen determination ($\text{N} \times 6.25$). Equal parts of the two products (described under "Part I" and "Part II"), by protein content, are combined. Dilutions are then made as in the general method.

The following preparations are listed separately from the protein extracts because they are more properly designated proteins:

Pseudodiphtheria bacillus (Corynebacterium pseudodiphtheriticum) Protein-Arco,² *Bacillus coli communis* (Escherichia coli) Protein-Arco,² *Friedlander bacillus* (Klebsiella pneumoniae) Protein-Arco,² *Micrococcus tetragenus* (Klebsiella pneumoniae) Protein-Arco,² *Micrococcus catarrhalis* (Klebsiella pneumoniae) Protein-Arco,² *Neisseria meningitidis* Type II Protein-Arco,² *Neisseria meningitidis* Type I Protein-Arco,² *Staphylococcus pyogenes aureus* (Staphylococcus aureus) Protein-Arco,² *Staphylococcus pyogenes albus* (Staphylococcus aureus) Protein-Arco,² *Streptococcus pyogenes* (Streptococcus pyogenes) Protein-Arco,² *Streptococcus hemolyticus* (Streptococcus pyogenes) Protein-Arco,² *Streptococcus non-hemolyticus* (Streptococcus pyogenes) Protein-Arco,² *Streptococcus viridans* (Viridans Streptococcus) Protein-Arco,²

The preparations marked 23 are prepared according to a standard method; viz., growing on solid mediums, washing off with saline solution; 0.4 per cent of cresol is added and the suspension heated for one hour at from 62 to 65 C. In the case of the streptococcus and pneumococcus proteins the organisms are grown in broth, centrifuged out, the bacterial paste shaken in saline solution and then treated in the same manner as described in the preceding sentence.

THE LABEL CLAIMS OF COSMETICS

Under the Food and Drugs Act of 1906 the cosmetic industry functioned with little or no restraint. Occasionally the unfair trade practice laws of the Federal Trade Commission were used to inhibit extraordinary claims and occasionally manufacturers stepped into therapeutic fields; otherwise there was practically no limitation on the use of misleading names or deceptive containers or foolish advertising claims. In 1938 the Wheeler-Lea Act and the new Food, Drug and Cosmetic Act were passed. Now the Federal Trade Commission can require a manufacturer to show cause for certain claims. If such cause cannot be shown, a stipulation or a cease and desist order is issued with a view to preventing such claims. Thus the Federal Trade Commission has ordered certain manufacturers not to use the word "nonallergic." The Federal Food and Drug Administration, which enforces the Food, Drug and Cosmetic Act of 1938, recently notified manufacturers, packers and distributors of cosmetics that certain names and statements used on the label of cosmetics contravene requirements of the statute which have now become effective. The official release states that:

The extent to which the use of such claims which may be regarded as false and misleading prevails suggests the propriety of a general notice to the trade to encourage appropriate label revision. It is, of course, not practicable to list all the claims that may be unwarranted; the following, however, are typical examples of some that are regarded as false or misleading:

Contour cream	Circulating cream
Crow's-foot cream	Enlarged pore preparations
Deep pore cleanser	Hair revitalizing preparations
Depilatories for permanent removal of hair	Muscle oil
Products represented as depilatories but which merely bleach the hair	Nourishing cream
Eyelash grower	Pore paste
Eye wrinkle cream	Skin conditioner
Hair color restorer	Skin firm
Hair grower	Skin food
Hair restorer	Skin texture preparations
Nail grower	Skin tonic
Nonallergic products	Stimulating cream
Peroxide cream	Tissue cream
Rejuvenating cream	Wrinkle eradicator
Scalp food	Cosmetics represented as valuable because of their vitamin content

A number of preparations have also been encountered which appear to be misbranded because they are represented as containing ingredients not actually present or present in insignificant proportions.

The designation of a product by the name of one ingredient, to the exclusion of all others, may also result in misbranding. Paragraph (b) under section 602 (A) of the general regulations for the enforcement of the Food, Drug and Cosmetic Act provides in part that "the labeling of a cosmetic which contains two or more ingredients may be misleading by reason (among other reasons) of the designation of such cosmetic in such labeling by a name which includes or suggests the name of one or more but not all such ingredients."

Formerly cosmetics were not advertised particularly to the medical profession. Then it was realized that physicians are interested in cosmetics, particularly from the point of view of allergy. The Board of Trustees of the American Medical Association recognized the necessity for expert advice in this field and created an Advisory Committee on Advertising of Cosmetics and Soaps, whose function it is to advise THE JOURNAL concerning the cosmetic products that are advertised in its pages. One of the first problems attacked was the question of allergy. In 1937 the committee stated that it was unable to accept any statement to the effect that a product was "nonallergic," because even the simplest preparation may be allergenic to susceptible persons. In addition the committee had opposed the promotion of such items as "skin fresheners" and "tissue creams," since there is no evidence that tissue can be nourished or skin freshened by cosmetic preparations. In similar vein the committee has held that such terms as hair or scalp tonics or lotions for which therapeutic claims are made, such as treatment of falling hair, dandruff or scalp infections, are not acceptable for advertising. If these preparations are recommended for the treatment of skin diseases they come within the purview of the Council on Pharmacy and Chemistry.

Other problems concern "medicated cosmetics," astringents and lotions. If a product owes its action to the presence of a therapeutic substance, it may come within the purview of the drug section of the new law. The "antiperspirants" owe their value to the presence of a relatively large amount of aluminum salt, such as the chloride; possibly these may be classed as drugs rather than cosmetics.

Common usage determines the names of widely used products; it is not always easy to decide whether or not a word which has been long used is still misleading. For instance, the word "bracer" has been used to define a mildly astringent cosmetic preparation for the skin. From one point of view this word indicates that the skin will be endowed with some vague enhancement of tone or resistance. However, when used alone the word may simply convey the notion that the product is a cooling and slightly counterirritant preparation. Terms such as these create difficulty for any regulatory body. Manufacturers of cosmetics who have followed the decisions of the American Medical Association Advisory Committee on Advertising of Cosmetics and Soaps have in many instances anticipated the suggestions as to terminology just issued by the Food and Drug Administration.

THE LATE RESULTS OF ECLAMPSIA

A large percentage of patients who have eclampsia will develop and maintain a residual hypertension, and a considerable but smaller percentage will have persistent albuminuria.

Page and Cox¹ have analyzed the reports of thirty authors published in the last twenty years. The 3,800 subjects in the combined reports were patients with eclampsia or other hypertensive syndromes of pregnancy who had been subsequently examined over periods varying from several months to several years. The authors found that 43 per cent of 3,000 of these patients had residual hypertension. Of a smaller group of several hundred patients who had had urinalyses in the follow-up examinations, 14 per cent were found to have persistent albuminuria. The California investigators then report follow-up examinations on their own group of eclampsia patients observed at the Los Angeles County Hospital in the ten year period that ended with 1936. They were able to locate and reexamine ninety-six of these women, of whom only 55 per cent could be called normal; that is, they were free of hypertension or albuminuria while not pregnant or they had become pregnant without developing a toxemia syndrome. The remaining 45 per cent had permanent hypertension in the nonpregnant state or recurrent toxemias of late pregnancy, or both. True, this was an indigent group of patients who had frequent pregnancies and inadequate antepartum care. Necropsy indicated that the vascular lesions rather than kidney failure usually were the determining causes of death in these women.

Recently Browne and Dodds² reported follow-up studies varying from several months to twelve years of 400 preeclamptic, eclamptic, hypertensive, chronic nephritic and recurrently toxemic patients. Among the eclamptic and the preeclamptic patients in this group, hypertension was a residual lesion in 60.8 per cent and 50.9 per cent respectively. Not one case was found, however, of chronic glomerular nephritis resulting from eclampsia or preeclamptic toxemia.

The kidneys of women who died of eclampsia have been described many times in textbooks of pathology. Only within the last few years have the remote kidney lesions of eclampsia been described. Bell³ demonstrated that the basement membrane of the glomerular capillaries was thickened in fatal cases of both preeclampsia and eclampsia. Baird and Dunn⁴ promptly confirmed Bell's observations. A year later Wilbur⁵ confirmed Bell's observations and raised the question whether or not this thickened glomerular membrane ever again became normal.

Page and Cox have described the kidneys of twenty-six women who died with toxemia of pregnancy or who gave a reliable history of previous toxemia. Thickening of the glomerular capillary membrane was found in patients who had died many years after the toxemia of pregnancy occurred. Thickening of the glomerular capillary membrane in some degree was present also in a few of the eleven control cases studied. This thickening is not, therefore, specific to the toxemias of pregnancy; it may possibly have resulted from severe infections in the control subjects who were women who had been pregnant from one to ten times without any evidence of eclampsia. While theories have been advanced to explain this glomerular lesion, the evidence as yet does not seem sufficient. Hofbauer⁶ proposed that eclampsia is due to an excessive secretion of the posterior pituitary lobe. Severe renal lesions have been produced by Byrom⁷ in the rat by injections of solution of posterior pituitary, but they did not resemble those found in eclampsia. Page and Cox suggest that renal ischemia produced by the glomerular changes of eclampsia may be responsible for the hypertension observed in the acute stages and so, with the persistent thickening, might account for the residual hypertension.

Patients who have had eclamptic toxemias are likely to have toxemia again if they become pregnant. Therefore these women should be kept under observation after delivery longer than the usual period. They should not become pregnant again until at least a year has elapsed after childbirth and then only after careful examination indicates that they may stand the strain of another pregnancy.

HAVERHILL FEVER

(Erythema Arthriticum Epidemicum)

In January 1926 an epidemic of unusual fever occurred in a restricted area of Haverhill, Mass. The syndrome, described by Place, Sutton and Willner,¹ presented (1) an abrupt onset with chills, fever, malaise, vomiting and headache; (2) an early eruption, rubellaform or morbilliform, occurring first on the extremities and tending to become hemorrhagic; (3) a multiple arthritis of varying but often of a severe and crippling degree, and (4) a fever curve of abrupt rise, with remission in from two to five days, and after a few days of relative freedom from symptoms a recurrence with which the arthritic manifestations appeared.

Parker and Hudson² recovered from the blood and joint fluid of some of these patients a highly pleomorphic organism, which proved to be gram negative and required serum for its growth in artificial mediums.

1. Place, E. H.; Sutton, L. E., and Willner, Otto: Erythema Arthriticum Epidemicum; Preliminary Report, *Boston M. & S. J.* **104**: 285 (Feb. 18) 1926.

2. Parker, Frederick, Jr., and Hudson, N. Paul: The Etiology of Haverhill Fever (Erythema Arthriticum Epidemicum), *Am. J. Path.* **2**: 357 (Sept.) 1926.

These investigators named this organism *Haverhillia multiformis*, placing it in the family *Mycobacteriaceae* in the order *Actinomycetales*. Serum from the patients produced agglutination of a polyvalent antigen of this organism in from 1:50 to 1:100 dilution, while serum from normal persons failed to show agglutination. Although bacteriologic evidence was lacking, there was sufficient clinical evidence to regard the epidemic milk borne. These investigators considered the disease a new clinical entity, which they named erythema arthriticum epidemicum, or Haverhill fever.

At about the same time Levaditi³ described a case occurring in a laboratory worker who came in contact with rats. The clinical features of his case closely resembled those of Haverhill fever, and the organism recovered from the blood, which Levaditi named *Streptobacillus moniliformis*, presented characteristics similar to *Haverhillia multiformis*. The similarity between the Haverhill cases, the case described by Levaditi and the sporadic cases described in the literature as rat bite fever soon became evident.

Farrell, Lordi and Vogel⁴ in a recent article have collected from the literature thirteen sporadic cases of rat bite fever, to which they added one of their own in which an organism closely resembling *Haverhillia multiformis* has been demonstrated on cultures of blood or joint fluid. It appears that the *Streptothrix muris ratti* recovered by Schottmüller (1914) in one of his cases, as well as organisms reported by Blake, Litterer, Dick and Tunnicliff, Tunnicliff and Mayer and Ebert and Hesse, and *Haverhillia multiformis* are closely related if not identical strains. The *Streptobacillus moniliformis* first described by Levaditi in 1926 and the subsequent cases described by Teissier and by Lemierre undoubtedly belonged in the same category. Of the fourteen cases reviewed by Farrell and his associates there was a history of rat bite in ten and of weasel bite in one.

Hazard and Goodkind⁵ in 1932 described a sporadic case of erythema arthriticum epidemicum with recovery of *Haverhillia multiformis* on blood culture with no history of rat bite, and Scharles and Seastone⁶ in 1934 described a case of rat bite infection in a medical student in which a diagnosis of Haverhill fever was made by cultivation of the organism from joint fluid.

The investigations of Strangeways, of Tunnicliff and of Lemierre established that *Streptobacillus moniliformis* is one of the normal inhabitants of the nasopharynx of both the laboratory and the wild rat.

The use of the term "rat bite fever" in describing cases of Haverhill fever is, however, undesirable, as

pointed out by Farrell, because of the possibility of confusing it with sodoku, or the Japanese rat bite fever. Despite certain clinical similarities, the two appear to be distinct entities. Sodoku occurs only in sporadic form and only after a rat bite. The causative agent is a spirochete, *Spirillum minus*, which can be recovered from the blood but which has never been cultivated. There is a striking similarity in the remittent type of fever so characteristically constant in sodoku and frequently seen in Haverhill fever. Arthritis, which is the most persistent symptom in Haverhill fever, is absent in sodoku. Arsenical therapy acts as a specific in sodoku but not in Haverhill fever. Differential diagnosis is made by examination of blood smears, of blood and joint fluid cultures, and by inoculation of mice with blood or diseased tissue. The possible relationship between the two organisms was suggested by the case described by Mackie and McDermott⁷ but has not been sufficiently elucidated.

Current Comment

TECHNIC FOR THE ERYTHROCYTE SEDIMENTATION TEST

In the twenty years since the introduction of the blood sedimentation test by Fahraeus, several modifications have been introduced. Various theoretical corrections for cell volume, cell count, hemoglobin content and the like have been proposed but most who employ the test remain content with the simple technic of one of the more common methods. Hambleton and Christianson¹ have recently reviewed the different technics and have concluded that in the present state of knowledge there is no justification for correcting the observed sedimentation rate for the effects of cell volume, cell count or hemoglobin content. In comparing various anticoagulants, these investigators believe that isotonic oxalate or citrate solutions as used in the original Westergren technic are superior to heparin or to the dry citrates or oxalates. The major disadvantage of the Cutler technic compared with the Westergren method is in the short length of the tube. Finally, they conclude that all the significant clinical data which may be obtained by sedimentation procedures can be found by a single one hour reading by the Westergren technic. The proposed corrections, while theoretically advisable, actually lead in many instances to results of lesser clinical value by making the test more tedious to perform or less clear to interpret. They emphasize, however, that those who use the Westergren technic should take great care that the tubes are perfectly vertical during the test. This conclusion that the most commonly used sedimentation technic, without involving complicated corrective procedures, is the most valuable for clinical purposes furnishes welcome news to the vast majority of those using the blood sedimentation test in their office and hospital work.

ORGANIZATION SECTION

ECONOMICS OF THE PRACTICE OF RADIOLOGY

The Inter-Society Committee for Radiology, in an effort to obtain factual information concerning the practice of radiology, sent schedules to 1,434 members of the four radiologic societies, the American Roentgen Ray Society, the American Radium Society, the Radiological Society of North America and the American College of Radiology. A total of 876 completed schedules were returned by radiologists in every state in the United States. The following tabulation of the information furnished by these radiologists, who so generously took time to answer the fifty-one questions asked, makes available for the first time data concerning the economics of the practice of radiology.

REPRESENTATIVENESS

In any sample study it is a fundamental requisite that the sample be representative of the entire population from which the sample is taken; otherwise the tabulation of information will be biased. Too frequently fine statistical calculation must be used to test the representativeness of the sample because the characteristics of the entire population are unknown. Fortunately the distribution of physicians in the United States who specialize in radiology or devote special attention to radiology can be determined from the American Medical Directory, which lists all physicians in the United States.

The comparison of the distribution of radiologists (including those physicians devoting special attention to radiology as well as those who limit their practice to radiology) who returned completed schedules for this study with the distribution of all radiologists in the United States permits a ready determination of the representativeness of the sample. This comparative distribution is shown in table 1 according to geographic divisions and in table 2 according to population groups.

TABLE 1.—Distribution of Radiologists According to Geographic Divisions

Geographic Divisions	Number of Radiologists in the U. S.*	Per Cent	Number of Radiologists in Study	Per Cent
New England.....	178	8	61	7
Middle Atlantic.....	704	32	232	27
East North Central.....	444	20	200	23
West North Central.....	172	8	87	10
South Atlantic.....	220	10	73	8
East South Central.....	86	4	38	4
West South Central.....	147	7	55	6
Mountain.....	48	2	27	3
Pacific.....	192	9	103	12
Totals.....	2,191	100	876	100

* Based on the American Medical Directory, Fifteenth Edition, 1938.

Table 3 compares the age distribution of radiologists included in the study with the age distribution of specialists. It is apparent from the similarity of these comparisons that the sample of radiologists included in the study is representative of radiologists throughout the United States.

DISTRIBUTION OF RADIOLOGISTS

A brief sketch of the growth and changes that have taken place in the practice of radiology may be helpful

Prepared by the Bureau of Medical Economics from a compilation and analysis of data collected by the Inter-Society Committee for Radiology.

to a better understanding of the summary of information concerning the practice of radiology as reported by 876 radiologists.

Within a relatively short period of seven years the number of radiologists in the United States has more than doubled, increasing from 1,005 in 1931 to 2,191 in 1938, or an increase of 118 per cent as shown in table 4. During this same period the population of the

TABLE 2.—Distribution of Radiologists According to Population Groups

Totals.....	100	100

* Based on the American Medical Directory, Fifteenth Edition, 1938.

United States has increased by only about 5 per cent. Consequently the population per radiologist of 122,614 in 1931 was reduced to 58,821 persons for each radiologist by 1938.

Another rather significant development in the distribution of radiologists has been the trend toward an increase in the number of radiologists in communities with small populations. This may have been caused by a greater interest in radiology on the part of physicians who were formerly general practitioners in these smaller communities or by recognition on the part of radiologists of better opportunities in smaller communities. In either event the number of radiologists in communities with less than 25,000 population has increased most rapidly. As shown in table 5, the number of radiologists in communities with less than 5,000 population increased more than sixfold between 1931 and 1938.

Radiologists distribute themselves geographically in much the same manner as other specialists. However, a comparison of the distribution of radiologists and other specialists according to geographic divisions as reported in "The Distribution of Physicians in the United States" shows that there are proportionately more radiologists as compared with other specialists in the Middle Atlantic and Pacific states and proportionately fewer radiologists in the West North Central and East South Central states. Likewise there are proportionately more radiologists than other specialists in population groups of 25,000 to 100,000

NATURE OF A RADIOLOGIST'S PRACTICE

More than 75 per cent of the physicians who replied to the inquiry (656 out of 874) limit their practice solely to radiology. Indicative of the qualifications of these 656 radiologists is the fact that 605 are diplomates of the American Board of Radiology. The replies showed that the radiologists who also practice in some other field of medicine tend to choose either general

practice, surgery, internal medicine or pathology. Of 218 who replied that they also practice in some other field of medicine forty-eight chose general practice, forty-one surgery, thirty-seven internal medicine,

* Based on Distribution of Physicians in the United States (Revised) 1931, table 45. Data from the American Medical Directory, 1931.

twenty-seven pathology, thirteen dermatology, eight obstetrics, and the remaining forty-four replies were scattered among the other specialties.

By far the greater majority of radiologists practice both diagnostic and therapeutic radiology. Of 865

ogy it appears that the "average" radiologist is 49 years old and has specialized for eighteen years. It is significant that a radiologist selected at random will usually have eighteen years of experience as a specialist to offer as a guaranty of good service and sound therapeutic judgment.

By far the greater majority of radiologists practice individually and do not enter into partnership relations with other radiologists. Of 869 replies 715, or 82 per cent, reported that they had no partnership arrangement and 154, or 18 per cent, reported that they did have a partnership arrangement with other radiologists.

Clinical radiology is taught in medical schools by 176 radiologists, whereas 698 reported that they did not teach radiology.

THE RADIOLOGIST AND THE HOSPITAL

The hospital is an integral part of the practice of radiology, as indicated by the replies of 802 of 840 radiologists who stated that they were members of hospital staffs. Six hundred and twenty-three radiologists stated that they were heads of the department of radiology in the hospitals where they practiced. The radiologists who are members of hospital staffs but did not state that they were head of the department are presumably younger associates. Notwithstanding the con-

TABLE 4.—Radiologists in Relation to Population

Geographic Divisions	Population, 1930	Number of Radiologists, 1931	Population per Radiologist, 1931	Estimated Population, 1937	Number of Radiologists, 1938	Population per Radiologist, 1938	Increase in Number of Radiologists	Per Cent Increase in Number of Radiologists
New England.....	8,166,339	83	98,389	8,590,000	178	48,258	95	114
Middle Atlantic.....	26,260,750	279	94,124	27,442,000	704	38,980	425	152
East North Central.....	25,297,184	205	123,400	25,780,000	444	58,063	239	116
West North Central.....	13,296,915	83	160,203	13,802,000	172	80,244	89	107

Mountain.....	3,701,788	26	142,376	3,777,000	48	78,687	22	84
Pacific.....	8,194,433	102	80,337	8,783,000	192	45,744	90	88
	122,775,041	1,005	122,164	128,877,000	2,191	58,821	1,186	118

replies, ninety-three practiced diagnostic roentgenography only, forty-six practiced therapeutic radiology only and 726 practiced both. Of the 726 radiologists who practiced both diagnostic roentgenography and therapeutic radiology, 697 indicated the percentage of practice devoted to therapeutic radiology as shown in table 6.

The majority of radiologists apparently devote less than one third of their practice to therapeutic radiology.

As was shown in table 3, the age distribution of radiologists is quite similar to the age distribution of other specialists. The median age of all radiologists was 48 years in 1931, which was also the median age for all physicians as of that year. In the present study 865 radiologists indicated their age as shown in table 7. The median age distribution of these radiologists is 49 years. An examination of the age distribution of radiologists according to geographic divisions indicates that the younger radiologists are proportionately more numerous in the South Atlantic and Middle Atlantic states, while the older radiologists are proportionately more numerous in the New England and Mountain states.

The physicians who limit their practice to radiology indicated that they had specialized a median of 18 years. The distribution of the replies according to the length of time specializing in radiology is indicated in table 8.

From a comparison of the median age of radiologists reporting and the number of years specializing in radiol-

centration of the practice of radiology in hospitals, it is significant that 610 of the radiologists maintain private offices outside the hospitals.

With regard to the time spent in practice in a hospital, 175 radiologists reported that they spent full time in one hospital, 640 reported that they spent part time in one or more hospitals and sixty-one did not reply or

* Allocation of population based on method used in Distribution of Physicians in United States (Revised), p. 18.

had no hospital connections. The 640 radiologists working part time in one or more hospitals provide radiologic services for a total of 1,100 hospitals. The number of hospitals served on a part time basis by a radiologist is indicated in table 9. As shown, one half of the radiologists work part time in only one hospital and 98 per cent of all radiologists work on a part time basis in three hospitals or less.

A wide variety of hours daily spent in a hospital was reported by those radiologists working part time in one or more hospitals. The average time devoted by radiologists per hospital was about two hours. While a number of the radiologists worked a longer period in one hospital and a shorter period in others, for the

Totals.....	865	100

purposes of summation it may be said that each radiologist practices about two hours in each of two hospitals, or a total of four hours daily. (The radiologists practicing in three hospitals spend three hours, two hours and one hour respectively in each hospital; the radiologists working in two hospitals spend two hours in the first and one hour in the second hospital.)

The median bed capacity of hospitals that utilize the full time of a radiologist was 270 beds and the median bed capacity of the hospitals in which radiologists work part time was 145. The greater majority of hospitals with part time radiologists have less than 300 beds. The distribution of hospitals by bed capacity according to part time or full time practice of radiologists is shown in table 10.

THE STATUS OF THE HOSPITAL IN WHICH THE RADIOLOGIST PRACTICES

With regard to the approval for intern training by the Council on Medical Education and Hospitals of the American Medical Association of hospitals in which the radiologists practice, 577 radiologists reported that 930 of the hospitals in which they practice were so approved whereas 207 radiologists reported that 307 hospitals in which they practice were not approved. One hundred and eighty-four radiologists reported that they practice in hospitals where the Department of Radiology is approved by the Council on Medical Education and Hospitals for training of residents and 549 radiologists replied that their department of radiology was not approved for residencies in radiology. Since less than eighty hospitals have departments of radiology that are so approved, it is apparent that some of these replies are from two or more radiologists in the same hospital.

PROFESSIONAL PRACTICES IN THE HOSPITAL

In reply to the question "Are roentgen interpretations made by others than specialists in radiology in your hospital?" it was indicated that in 102 hospitals the roentgenologic interpretations are made by others than the radiologist, whereas in 1,148 hospitals the roentgenologic interpretations are made only by specialists in

practicing in 1,279 hospitals stated in reply to the question "Is every patient referred to the radiologic department considered as the case of the director of the department?" that in 1,079 of these hospitals the patients referred to the radiologic department were considered as cases of the head of the department and that in sixty-nine hospitals the patients were not considered the cases of the head of the department since other staff physicians may examine and treat patients in the department independent of the director or his assistants. Radiologists in the remaining 131 hospitals did not reply to the question.

The radiologists practicing in 661 hospitals indicated the percentage of hospital admissions that are referred for radiologic diagnosis. According to these replies, in the majority of hospitals about one third of the admissions are referred for radiologic diagnosis. The percentage of admissions as reported for the 661 hospitals was as follows: less than 20 per cent, 172 hospitals; from 20 to 49 per cent, 311 hospitals; from 50 to 79 per cent, 139 hospitals; from 80 to 100 per cent, thirty-nine hospitals.

With regard to participation of hospitals in hospital insurance plans, the radiologists replying for 1,099 hospitals stated that 553 hospitals in which they practice do participate in hospital insurance plans and that in 240 of these hospitals ordinary x-ray examinations are included as a hospital insurance plan benefit.

3.....	108		

The practice of including charges for diagnostic radiologic services in the per diem rate for the hospital room was reported by the radiologists to be the established rule in only fifty-five hospitals and that in thirty-two hospitals the diagnostic services were included in special arrangements such as flat rate plans for obstetric and workmen's compensation cases. In the remaining 1,131 hospitals, charges for diagnostic services were reported not to be included in the per diem rate for hospital services.

Concerning payments for services rendered to charity patients in hospitals, 111 radiologists replied that they did receive payments and 550 replied that they did not receive payments for such services. The 111 radiologists who received payments for charity services practice in 158 hospitals, whereas the 550 radiologists who replied that they did not receive payments for charity services practice in 936 hospitals.

With regard to the rendering of bills and the collection of fees for services of radiologists in hospitals, 130

TABLE 10.—*Bed Capacity of Hospitals in Which Radiologists Practice Full or Part Time*

Bed Capacity	Number of Hospitals in Which Radiologists Practice Full Time	Number of Hospitals in Which Radiologists Practice Part Time
1-99.....	21	286
100-249.....	54	456
250-399.....	34	141
400-749.....	38	77
750 and over.....	13	51
Totals.....	160	1,011

radiologists (19 per cent) replied that they send their own bills, 518 (77 per cent) reported that the hospital collects the fees for these services on its billhead and twenty-six (4 per cent) indicated that both the hospital and the physician collect fees for radiologic services. In connection with the replies that the hospital collects fees for services on its billhead, 3 per cent of the physicians stated that the hospital collects for x-ray diagnostic services only. The physicians who send their own bills for collection of fees for radiologic services in hospitals practice in 197 hospitals, whereas physicians who indicated that the hospital collects fees for radiologic services on its billhead practice in 845 hospitals.

A total of 759 radiologists answered the question "Who owns the x-ray equipment in the hospital?" Of these replies 635, or 84 per cent, stated that the hospital owned the equipment, ninety-one (12 per cent) that the radiologist owns the equipment and thirty-three (4 per cent) that both the radiologist and the hospital own the equipment. Considering the number of hospitals, these replies indicated that in 999 (83 per cent) hospitals the hospital owns the x-ray equipment, in 144 (12 per cent) the radiologist owns the equipment and in fifty-nine (5 per cent) both the hospital and the radiologist own the equipment. The American Hospital Association in a study of reports for hospitals obtained by the American College of Surgeons in 1936¹ found that for 1,856 hospital administrators who answered the question "Who owns your x-ray equipment?" 1,745 stated that the x-ray equipment was owned by the hospital and 111 replied that it was owned by the radiologist. The study by the American Hospital Association would therefore show that 94 per cent of the hospitals owned the x-ray equipment but there was no indication of joint ownership by both the hospital and the physician as shown in the replies furnished by the radiologists in the present study.

It appears that the nature of the agreements between hospitals and radiologists is an oral understanding, as only one fourth of the radiologists replied that they had a written contract with the hospital. Where the radiologist does have a written contract with the hospital, the length of time for which the contract is made is usually one year. Several of the contracts were for five or ten year periods and the average length of time reported

for all written contracts was four years. Approximately one fourth of the written contracts do not specify a limit on the time for which the contract is made.

PAYMENT ARRANGEMENTS WITH HOSPITALS

Some of the most interesting questions concerned the payment arrangements that radiologists have with hospitals. The reports from 687 radiologists indicated the nature of the financial arrangements with the hospitals in which radiologists practice. Table 11 shows the tabulation of the replies according to the type of financial arrangement and indicates whether the radiologist practiced full time or part time in the hospital.

This table indicates that the percentage type of payment arrangement was most frequently reported by the radiologists. Under such an arrangement the radiologist and the hospital each receive a certain percentage of the income for the department of radiology. The percentage division is usually calculated on the basis of gross income, since more than two thirds of the percentage arrangements were determined as a percentage of gross income, whereas about one third was a percentage of the net income.

The next most important type of payment arrangement is on a salary basis. Approximately 44 per cent of the replies indicated that a salary or a salary and commission was the financial arrangement between the radiologists and the hospitals. Under the salary arrangement the hospital collects all charges and pays the radiologist a specified annual sum. Under the salary and commission arrangement the radiologist receives an annual sum but in addition is paid a certain percentage or a commission according to the volume of income or the number of patients treated. The remaining 9 per cent of the radiologists reported a rental or lease arrangement with the hospital. Under the rental or lease arrangement the radiologist collects the fees and reimburses the hospital for the use of space or space and equipment.

The reports from 189 radiologists, which were not included in this table of financial arrangements, includes

TABLE 11.—*Financial Arrangements with Hospitals (According to Number of Radiologists)*

those radiologists who had no hospital connections as well as those who gave no information concerning payment arrangements or suggested some rather special types of arrangements. The "some other basis" answers included statements such as:

Personal fees.

No payment whatever (forty-seven of the reports stated that services were given without remuneration).

Partnership.

First \$10,000 goes to hospital, remainder to the department of radiology.

All receipts, after deducting expenses and setting aside a sum for new equipment, goes to the department.

1. Report of Study on Relations of Hospitals and Radiologists, Hospitals 11: 50 (Nov.) 1937.

Many of these 189 replies indicated that the radiologist practiced on a private consultant basis, charging and collecting his professional fee without any financial arrangement with the hospital.

Under the percentage basis of payment the amount of gross income that was received by the radiologist varied from 22 to 80 per cent, with 50 per cent as the most usual percentage. The proportion of net income that was received by the radiologist varied from 33 to 66 per cent, with 50 per cent again the most usual arrangement.

TABLE 12.—Financial Arrangements with Hospitals (According to Number of Hospitals)

Type of Arrangement	Hospitals	Per Cent

Percentage not indicated.....	18	1.7
Rental or lease.....	605	55.1
	96	8.7
	1,008	100.0

Table 11 also shows that a salary arrangement is the most customary payment basis for a radiologist who practices full time in a hospital, whereas a percentage basis is most frequently reported by the radiologist who practices on a part time basis. As many radiologists practice in more than one hospital, it was necessary to make a special tabulation of the payment arrangements for all replies when the radiologists worked in two or more hospitals. In some instances the radiologist had one type of arrangement with one hospital and another with the second or third hospital. For all such duplicating payment arrangements 68 per cent were on a percentage, 19 per cent on a salary, 5 per cent on a salary plus commission and 8 per cent on a rental or lease payment basis.

The total of all types of financial arrangements with hospitals is shown in table 12, in which the financial arrangements are tabulated according to the number of hospitals.

As shown by this table, 55 per cent of the payment arrangements with radiologists who practice in hospitals are on a percentage basis. In slightly more than 36 per cent of the hospitals the radiologists receive a salary or a salary plus commission. In about 9 per cent of the hospitals the payment arrangement is on a rental or lease basis. The 181 hospitals not included in the tabulation are those hospitals in which the radiologists reported that their services were given free or that some special payment arrangement was in effect.

The information obtained by these tabulations of reports from radiologists throws considerable light on the prevailing practices in hospitals for the remuneration of radiologists. There appears to be no doubt that the most usual payment arrangements is for the radiologist to receive a percentage of the gross income obtained in the department of radiology.

MISCELLANEOUS

In addition to the questions requesting information concerning arrangements for the practice of radiology there were some questions asking for miscellaneous information pertinent to the economics of the practice of radiology. For example, questions were asked about the amount of radium owned by the radiologist, whether the radiologist carried malpractice insurance and the amount of such insurance, and the gross and net income

received during the year. The nature of the information obtained in reply to these questions was not suitable for tabulation. The large number of variables involved and the uncertain accuracy of some of the information recorded made any complete tabulation questionable in value.

SUMMARY

Information concerning the economics of the practice of radiology was obtained from 876 completed schedules returned by radiologists in every state in the United States.

Analysis of the completed schedules indicates that the information is representative of the practice of radiology in the United States because the distribution of the radiologists in the sample compared with the distribution of all radiologists in the United States according to factors such as age and location of radiologists in geographic divisions and population groups.

Within a relatively short period of seven years the number of radiologists in the United States has more than doubled, increasing from 1,005 in 1931 to 2,191 in 1938, or an increase of 118 per cent as shown in table 4. During the same period the population of the United States has increased by only 5 per cent.

Another significant development in the distribution of radiologists has been the trend toward an increase in the number of radiologists in communities with small populations. The number of radiologists in communities of less than 5,000 population has increased more than 600 per cent between 1931 and 1938, while the increase in communities with more than 100,000 population was less than 1 per cent.

While the distribution of radiologists is very similar to the distribution of other specialists, there are proportionately more radiologists as compared with other specialists in the Mid-Atlantic and Pacific sections and proportionately fewer radiologists in the North West Central and East South Central states.

The radiologists who were not limiting their practice solely to radiology chose either general practice, surgery, internal medicine or pathology most frequently in the order named.

The "average" radiologist is 49 years old and has specialized for eighteen years. It is significant that a radiologist selected at random will usually have eighteen years of experience as a specialist to offer as a guaranty of good service and sound therapeutic judgment.

In his relations with the hospitals the radiologist is most likely to work part time in one or more hospitals. The number of hospitals in which a radiologist practices and the amount of time spent in each hospital vary considerably. However, for the purposes of summation it may be said that the radiologist practices for about two hours in each of two hospitals, or a total of four hours daily in the hospital. In addition, the greater majority of radiologists maintain private offices outside of hospitals.

With regard to the professional practices within the hospital, radiologists indicated that in by far the greater number of hospitals the patients referred to the radiology department were considered as cases of the head of the department. The replies also indicated that about one third of the admissions were referred for radiologic diagnosis. The replies also showed that in most hospitals diagnostic radiologic services are not included in the per diem rate for hospital services.

A total of 550 radiologists of 661 replying stated that they received no payments for charity services in the hospital.

ORGANIZATION SECTION

JOUR. A. M. A.
SEPT. 2, 1939

Prevailing practice in the collection of fees for services of radiologists is to include the fees in the bills that the hospitals send to the patients.

A total of 84 per cent of the radiologists representing 83 per cent of the hospitals stated that the x-ray equipment in the hospital was owned by the hospital. In the remaining hospitals the equipment is owned by the radiologist or jointly by the radiologist and the hospital.

The working agreement between the hospital and the radiologist is usually an oral understanding, as only about one fourth of the radiologists replied that they had a written contract with the hospital. The length of time for such a contract is usually one year.

Concerning the payment arrangement between the radiologist and the hospital, the most usual arrangement

is for the radiologist to receive a percentage of the gross income received in the department of radiology. This percentage is customarily 50. A tabulation of the financial arrangements with hospitals according to the number of radiologists indicated that about 44 per cent of the radiologists received a salary or a salary plus commission, 47 per cent received a percentage of the gross or net income and 9 per cent were on a rental or lease basis.

A tabulation according to the number of hospitals indicates that 55 per cent of the radiologists receive a percentage of the gross or net income, in 36 per cent of the hospitals radiologists are remunerated on a salary or a salary plus commission basis, and in 9 per cent the financial arrangement is on a rental or lease basis.

MEDICAL ECONOMIC ABSTRACTS

TUBERCULOSIS CARE IN NEW YORK CITY

Dr. S. S. Goldwater, Commissioner of Hospitals, denies the alarmist reports concerning the prevalence of tuberculosis in New York City that are being circulated by pressure groups. These reports claim that there has been an increase in deaths from tuberculosis in recent years, but the Department of Health states that 4,056 deaths were caused by pulmonary tuberculosis in New York City in 1933 as compared with 3,481 during 1938.

PREVENTION UNDER BRITISH HEALTH INSURANCE

The Cheshire Panel Committee on May 22 published what it called a "Medical Testament," signed by its thirty-one members and dealing with nutrition in relation to agriculture. This "testament," which appears in the supplement to the *British Medical Journal* for April 15, states that the investigation on which the report was based was to determine how far the National Insurance Act has fulfilled the object announced in its title—"the Prevention and Cure of Sickness." The "Testament" says

Of the first item, "the prevention . . . of sickness," it is not possible to say that the promise of the bill has been fulfilled. Though to the sick man the doctor may point out the causes of his sickness, his present necessity is paramount and the moment is seldom opportune, even if not altogether too late, for any essay in preventive medicine. On that first and major count the act has done nothing. We feel that the fact should be faced. Our daily work brings us repeatedly to the same point: "This illness results from a lifetime of wrong nutrition!" The wrong nutrition begins before life begins. "Unfit to be a mother"—from undernutrition or nutritional anaemia—is an occasional verdict upon a maternal death. For one such fatal case there are hundreds of less severity where the frail mothers and sickly infants survive.

After a discussion of the effects of food deficiency as shown in the four items bad teeth, rickets, anemia and constipation, the concluding paragraph says:

We cannot do more than point to the means of health. Their production and supply are not our function. We are called upon to cure sickness. We conceive it to be our duty in the present state of knowledge to point out that much, perhaps most, of this sickness is preventable and would be prevented by the right feeding of our people. . . .

which Dr. Haven Emerson, director of the Columbia University Institute of Public Health, is chairman, reported that New York City had provided almost as many beds in tuberculosis institutions as there are annual deaths from this disease; this is the standard for hospital accommodations long accepted by tuberculosis experts. The committee urged the city to provide 2,500 additional beds, and of these the department has already provided or has under way 1,673.

Dr. Goldwater states that:

1. For the first time in its history, the department has integrated all its tuberculosis services in a single administrative division under a full-time director. As a result of this reorganization, substantial improvements have been effected in administrative procedures as well as in clinical methods.
2. The Emerson committee recommended that the Hospital Admission Bureau, formerly operated jointly by Health and Hospitals, be placed under the direct jurisdiction of the Department of Health. With the consent of the Commissioner of Health, this change has been effected.
3. Under the present vigorous administration of the Department of Health, a case-finding program unparalleled in the history of the city of New York has been under way for several years. Nevertheless, the waiting list of nonhospitalized cases

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Society News.—The Alabama State Pediatric Association will hold its annual meeting at the Hillman Hospital, Birmingham, September 7, with Dr. Angus M. McBryde, Durham, N. C., the guest speaker. Dr. McBryde will conduct a clinic in the afternoon and deliver an address in the evening. There also will be a round table discussion on sulfanilamide, neoprontosil and sulfapyridine and a symposium on nutrition.

CALIFORNIA

Changes in Health Officers.—Dr. Harold R. Hennessy, Yuba City, has been appointed health officer of Sutter County, effective July 1, succeeding Dr. Francis P. Wisner, Yuba City. According to the *Weekly Bulletin* of the state department of health, Sutter County is joined with Yuba County in a full time county health unit and Dr. Hennessy will serve as health officer of both counties under the consolidation. Dr. Lloyd N. Tarr, Taft, has been appointed health officer of that town, succeeding Dr. Oran Newton.

Governor Vetoes Bill to Require Citizenship.—Governor Olson disapproved by a pocket veto a bill passed by the recent state assembly requiring citizenship in the United States of applicants to practice medicine in California. The governor in a statement reported in the *Sacramento Bee* July 26 gave it as his opinion that the bill would "eliminate practice by some of the world's greatest scientists." He said also that "it would work a hardship on other qualifying physicians by compelling a wait of several years necessary to acquire citizenship before being permitted to earn a livelihood in their own profession." Finally he pointed out that the federal government has control of the admission of aliens and that "the states should not, and probably as a matter of constitutional law cannot, deny such aliens a right to earn a livelihood in any proper pursuit."

CONNECTICUT

Annual Clinical Congress.—The fifth Clinical Congress of the Connecticut State Medical Society will be held in New Haven September 19-21. Formal addresses and five minute talks will make up the morning programs, with panel discussions for the afternoons. Section meetings will be held Wednesday evening September 20. Guest speakers at the morning sessions will be:

Dr. James H. Wall, White Plains, N. Y., Problems in Clinical Medicine That Respond to a Psychiatrist
Dr. Clay Ray Murray, New York, Fractures
Dr. Harry H. Gordon, New York, Fractures in the Newborn Infant
Dr. William E. Gye, director, Imperial Cancer Research Fund, London, Problems in the Etiology of Cancer
Dr. Ralph M. Waters, Madison, Wis., Relation of Pain-Relieving Drugs to Respiratory Morbidity
Dr. Joseph Millett, Hempstead, N. Y., Newer Sulfanilamide Drugs—Recent Advances in Chemotherapy
Dr. George H. Gehrmann, Wilmington, Del., Industrial Poisons
Dr. Henry W. Cave, New York, Gallbladder Disease: To Operate or Not to Operate, with Particular Reference to Acute Cholecystitis
Dr. Paul Titus, Pittsburgh, The Examining Boards in the Various Specialties

Subjects of the panel discussions will be: medical progress in 1939, surgical progress in 1939, modern anesthesia, drug toxicity, industrial poisons, obstetrics, and normal and pathologic gallbladder with its dependent biliary ducts. There will be special courses for the three days on endocrinology, cancer, neonatal pediatrics, problems in clinical medicine encountered by the psychiatrist and treatment of fractures.

ILLINOIS

State Diagnostic Laboratories.—The state department of health has issued a list of laboratories that it has approved for making blood tests for syphilis and microscopic tests for gonorrhea, as required by the laws pertaining to expectant mothers and pre-nuptial physical examinations. A law recently enacted requires pregnant women to have a blood test for syphilis and specifies that the test must be made in an approved laboratory. The law on premarital examinations was recently amended to require also that the tests be made by approved laboratories. About two years ago the health department organized a committee to set up standards for local labora-

tories and appointed a trained laboratory specialist to inspect them. All laboratories offering to perform tests for syphilis and gonorrhea were invited to register and apply for certificates of approval. Certificates have now been issued to eighty-five laboratories, forty-eight in Chicago and thirty-seven down state. About 16 per cent of those that applied for certificates failed to meet the standards when first investigated, the health department reported. To aid laboratories in qualifying, the department offers special courses of training to employees, provides a specialist to inspect and make recommendations for improvement and provides certain materials necessary for making blood tests. There are 141 other local diagnostic laboratories that have not been approved, according to the *Illinois Health Messenger*.

CHICAGO

Annual Symposium on Industrial Medicine.—The department of industrial medicine of Northwestern University Medical School will present its third annual Symposium on Industrial Disease and Hygiene September 25-26 at Thorne Hall on the Chicago campus. Chairmen for the four sessions will be Drs. Merritt Paul Starr, assistant professor of medicine at Northwestern; Wilber E. Post, clinical professor of medicine, Rush Medical College; Edward A. Oliver, associate clinical professor of dermatology, Rush, and M. Herbert Barker, assistant professor of medicine, Northwestern. Subjects and speakers are:

Nontuberculous Pulmonary Diseases, Drs. Ernest E. Irons and Hollis E. Potter.
Kidney Diseases of Midlife, Drs. Herman O. Mosenthal, New York, and James P. Simonds.
Soap—A Cleanser and an Irritant and Its Role in Occupational Dermatitis, Dr. James Herbert Mitchell.
Welding—Gas and Electric, Drs. Eugene L. Walsh and James A. Britton.
Common Beneficent Uses of Poisonous Metals and Alkaloids—Economic Importance and Health Hazards, Marcus A. Grossmann, Sc.D., and Dr. Adolph G. Kammer, Chicago; Mr. C. R. Cleveland, entomologist of the Standard Oil Company, and Warren A. Ruth, Ph.D., professor of pomological physiology, University of Illinois.

There will be a banquet session at the Blackstone Hotel Tuesday evening September 26 with Dr. Walter L. Bierring, Des Moines, Iowa, as the speaker on "The Past and Future of Preventive Medicine." Dr. Irving S. Cutter, dean of the Northwestern medical school, will be toastmaster.

IOWA

Society News.—Dr. Thomas Parran, surgeon general of the U. S. Public Health Service, Washington, D. C., will be the guest speaker on the first fall program of the Linn County Medical Society, Cedar Rapids, September 7.—Dr. Stuart C. Cullen, Iowa City, addressed a combined meeting of the Bremer County Medical County and the staff of Mercy Hospital, Waverly, July 26, on "Newer Anesthetic Agents and Technics."—Dr. John T. Strawn, Des Moines, addressed the Calhoun County Medical Society July 18 at Rockwell City on "Gastric Hemorrhages."—At a meeting of the Dallas-Guthrie Counties Medical Society in Woodward, July 27, the speakers were Dr. Dwight C. Wirtz, Des Moines, on "Use of Pins and Skeletal Traction in Fractures" and Harold M. Skeels, Ph.D., Iowa City, "Mental Growth of Children in Relations and Differentials of the Environment."

KENTUCKY

State Medical Meeting in Bowling Green.—The Kentucky State Medical Association will hold its annual meeting in Bowling Green September 11-14 under the presidency of Dr. John W. Scott, Lexington. The guest speakers will be:

Dr. Roger I. Lee, Boston, Treatment of Artificial Menopause.
Dr. Louis Hamman, Baltimore, Problems in Hematological Diagnosis.
Dr. Donald Guthrie, Sayre, Pa., Cancer of the Breast.
Dr. Milton B. Cohen, Cleveland, Newer Concepts of Allergy.

In addition to Dr. Cohen, participants in a symposium on allergy will be Drs. Frank A. Simon, Armand E. Cohen, Adolph B. Loveman and Irving Rosenbaum Jr., Louisville. The oration in surgery will be delivered by Dr. Rettig Arnold Griswold, Louisville, on "Principles in the Treatment of Fractures" and the oration in medicine by Dr. Edward B. Willingham, Paducah, on "Infection as the Etiological Factor in Heart Disease." Among other Kentucky physicians on the program are:

Dr. Hoy Newman, Bowling Green, Pituitary Adenoma and X-Ray Therapy of the Disease.
Dr. James Murray Kinsman, Louisville, Sulfapyridine Indications, Bad Effects and Methods of Administration.
Dr. William R. Parks, Harlan, Management of Pneumonia in Small Urban Communities.
Dr. John H. Blackburn, Bowling Green, The Patient a Personality, Not a Machine.
Dr. David L. Jones, Fulton, Swine Erysipelas in Man.
Dr. Bernard J. Baute, Lebanon, Autotransfusion, A Life-Saving Procedure.

LOUISIANA

Personal.—Dr. Joseph Rigney D'Aunoy, dean and professor of pathology and bacteriology, Louisiana State University Medical Center, New Orleans, has been decorated with the Order of Commendatore of the Crown of Italy "in recognition of his achievements in the fields of medical research and education."

Dr. Lorio Indicted on Federal Charge.—Dr. Clarence A. Lorio, Baton Rouge, was indicted by a federal grand jury in Louisiana August 21 on a charge of using the mails to defraud. He was accused of using his influence at Louisiana State University to gain approval of electrical contracts on raised bids, splitting half of a profit of \$12,600 obtained through this work, according to the *New York Times*. Dr. Lorio was already under state indictment for alleged embezzlement of university funds (*THE JOURNAL*, July 22, p. 340).

MAINE

Society News.—Dr. Walter S. Stinchfield, Skowhegan, was elected president of the Maine Medicolegal Society at the annual meeting in conjunction with the meeting of the Maine Medical Association in June. Franz U. Burkett, Augusta, was elected vice president and Dr. George L. Pratt, Farmington, secretary.—The Kennebec, Penobscot, Piscataquis and Somerset county medical associations held a joint meeting at Squaw Mountain Inn, Greenville, July 19. Drs. George L. Pratt, Farmington, president of the state medical association; Frederick R. Carter, Augusta, secretary, and Penry L. B. Ebbett, Houlton, chairman of the council, spoke on association activities and the following scientific program was presented: Drs. Carl C. Corson, Portland, "Fractures of the Spine"; William V. Cox, Lewiston, "Diagnostic Signs as Evidenced by Visual Field and Fundus"; Forrest B. Ames, Bangor, "X-Ray in Fractures," and Allan Woodcock, Bangor, "General Fracture Principles."—The Maine Hospital Association held its annual meeting August 30 at Lakewood. Among other features was a panel discussion on "Improving the Hospital Through Elevation of Professional Standards."

MICHIGAN

Poliomyelitis Delays Opening of Schools.—The Detroit Board of Education acting on advice from the city board of health has ordered the opening of schools in Detroit postponed until September 18 because of the prevalence of poliomyelitis, it was announced August 24. Schools in suburban communities planned to open on schedule, as did Wayne University. The number of active cases August 25 was ninety-three and the total number since January 1 was 274.

State Medical Meeting in Grand Rapids.—The annual meeting of the Michigan State Medical Society will be held in Grand Rapids September 18-22, with headquarters at the Pantlind Hotel and sessions at the Civic Auditorium. There will be about forty guest speakers at general assemblies and all section meetings will be held Wednesday morning September 20. Dr. Rock Sleyster, Wauwatosa, Wis., President of the American Medical Association, will deliver the Andrew P. Biddle Oration and Dr. Henry A. Luce, Detroit, will deliver his official address as president of the society at a general assembly Wednesday evening. Dr. Biddle will present the Biddle Oration Scroll to Dr. Sleyster, whose subject will be "What Price Depression?" Among the guests will be:

- Dr. James R. Goodall, Montreal, Que., Endocrinology—Its Application to Human Needs.
- Dr. Edwin E. Osgood, Portland, Ore., Evaluation of Total, Differential and Absolute Counts.
- Dr. Harold I. Lillie, Rochester, Minn., Certain Symptoms Common to the Nose, Throat and Ear—A Pathologic Basis.
- Dr. James W. Smith, New York, Strabismus in Children.
- Dr. Walter W. Smith, Minneapolis, Minn., Differential Diagnosis and Treatment of Strabismus.
- Dr. Anthony Sindoni Jr., Philadelphia, Prenatal and Postnatal Care of a Pregnant Diabetic Woman.
- Dr. Louis Schwartz, U. S. Public Health Service, Bethesda, Md., Occupational Dermatoses.
- Dr. Harold N. Cole, Cleveland, Importance of Latent Syphilis from the Standpoint of the General Practitioner.
- Dr. McIver Woody, New York, Sickness Disability Among Wage Earners.
- Dr. Carl P. Huber, Indianapolis, Recent Trends in the Investigation and Treatment of Sterility.
- Dr. Robert C. Hood, Washington, D. C., State Programs of Service for Crippled Children Under the Social Security Act.
- Dr. Philip Lewin, Chicago, Prevention and Cure of Deformity After Poliomyelitis.
- Dr. Jonathan C. Meakins, Montreal, Que., Gastrointestinal and Hepatic Function in Constrictive Circulatory Failure.
- Dr. Maxwell Finland, Boston, Treatment of Pneumonia with Sulfapyridine and Specific Serum.

Mr. Thomas A. Hendricks, Indianapolis, executive secretary of the Indiana State Medical Association, will be the guest speaker at a conference of county society secretaries on "How Not to Make Laws and Influence Legislation."

MINNESOTA

Abortionist Nellesen Sentenced.—Peter H. Nellesen, aged 68, St. Paul, was sentenced to a term of not less than ten and not more than fifteen years at hard labor in the state prison at Stillwater, July 25. Nellesen pleaded guilty to a charge of manslaughter in the first degree following the death of a young woman from a criminal operation. He admitted receiving \$15 for the operation. Nellesen served a previous term of three years in the state prison at Stillwater, after he pleaded guilty to information charging him with abortion. He does not hold a license to practice any form of healing in Minnesota. He stated that about forty years ago he worked for a number of years as a male nurse at the Soldiers' Home at Minnehaha Falls. According to the records of the police department, Nellesen has had six previous convictions on various liquor law charges, the sentences ranging from five months in the county jail to eighteen months in the federal penitentiary at Leavenworth.

NEW JERSEY

Another Medical Supplement.—A health section, prepared by the Atlantic County Medical Society under the supervision of the publications committee headed by Dr. Samuel Barbashi, was published by the *Atlantic City Press* on June 9. It was dedicated to the Medical Society of New Jersey, which was holding its annual session there at the time. The supplement, in tabloid form, had twenty-eight pages. Most of the articles were signed by members of the society.

NEW YORK

Society News.—Dr. Sidney P. Schwartz, New York, addressed the Medical Society of the County of Rockland at its summer meeting at Sparkill, July 12, on "Treatment of Acute Cardiovascular Emergencies."—Dr. William J. Hoffman, New York, gave a lecture on cancer at a special meeting of the Schoharie County Medical Society July 19 in Cobleskill.—William F. Martin, New York, counsel for the state medical society, addressed the quarterly meeting of the Ontario County Medical Society in Geneva July 11 on "Medical Jurisprudence." A forum discussion on childbearing was also presented.

Pediatrics for County Societies.—A series of lectures on pediatrics is in progress for the Schoharie County Medical Society at Cobleskill Thursday afternoons and the Delaware County Medical Society at Delhi Thursday evenings. The lecturers are:

- Dr. Marjorie F. Murray, Cooperstown, Physical Examination of Children, August 10.
- Dr. Paul W. Beaven, Rochester, Deficiency Diseases of Childhood, August 17.
- Dr. Abraham C. Silverman, Syracuse, Infectious Diseases of Childhood, August 24.
- Dr. Charles Hendee Smith, New York, Diet in Infancy and Childhood, August 31.
- Dr. Albert D. Kaiser, Rochester, Rheumatic Fever and Heart Diseases, September 7.

New York City

Study of Hospital Diagnoses.—The Research Bureau of the Welfare Council of New York City has published a preliminary report of a study of the causes of illness as seen in 113 hospitals in a year. The object of the study was to provide a guide for the classification and tabulation of hospital discharges. The list contains 433 items. Data were collected and tabulated by WPA research and clerical workers. The institutions studied included both municipal and voluntary hospitals and comprised 89.5 per cent of the total bed capacity of all hospitals in the city. The study covered the illnesses of 576,623 patients. Dr. Haven Emerson was chairman of a special technical advisory committee which included also Drs. Ernst P. Boas, George Baehr and Marta Fraenkel.

Graduate Fortnight Program.—The Twelfth Graduate Fortnight of the New York Academy of Medicine will be held October 23 to November 3. The general subject will be "The Endocrine Glands and Their Disorders" and the speakers will be Drs. Herbert M. Evans, Berkeley, Calif.; James B. Collip, Montreal, Que.; Elmer L. Sevringhaus, Madison, Wis.; James H. Means, Frank H. Lahey and Walter B. Cannon, Boston; Cyril N. H. Long and John F. Fulton, New Haven, Conn.; Hugh H. Young and William G. MacCallum, Baltimore; Rollin T. Woodyatt and Carl R. Moore, Ph.D., Chicago; Drs. Leopold Lichtwitz, Leo M. Davidoff, David Marinc, Harold Thomas Hyman, Robert F. Loeb, Bernard S. Oppenheimer, Robert T. Frank, Ephraim Shorr, Henry L. Jaffe and Philip E. Smith, Ph.D., all of New York. Fifteen hospitals will present coordinated afternoon clinics and demonstrations. A program may be obtained from the academy, 2 East One Hundred and Third Street.

NORTH CAROLINA

Society News.—Dr. Hermon Marshall Taylor, Jacksonville, Fla., presented a motion picture film on "Effects of Swimming on the Respiratory Tract" at a meeting of the Buncombe County Medical Society, Asheville, August 7. In addition, a program of case reports was presented. The society held its first annual golf tournament at the Asheville Country Club August 21.

Laboratories Approved for Wassermann Tests.—A list of thirty-one laboratories distributed throughout North Carolina has been approved by the state board of health for making Wassermann tests for candidates for marriage. Until these laboratories were investigated and approved all tests had to be made at the state laboratory in Raleigh, necessitating delays and placing a heavy load on the central laboratory. All the approved laboratories will be required to participate in evaluation studies, and if at any time one should lack proficiency it will be stricken from the approved list.

Wake Forest College to Move to Winston-Salem.—Wake Forest College School of Medical Sciences, Wake Forest, is to be moved to Winston-Salem and expanded to a four year school, newspapers announced August 6. Funds have been provided by the Bowman Gray Fund from the estate of the late Mr. Gray, a tobacco magnate of Winston-Salem. The amount of the gift was not disclosed, but it was said to be adequate to develop the school to a capacity of 200 students and to operate it. Hospital facilities will be provided by the North Carolina Baptist Hospital, an institution of 108 beds, and it is expected that affiliations with other Winston-Salem hospitals will be established. Tentative plans for a medical building on property of the Baptist Hospital were said to be under way. It was estimated that the school would be ready to operate by the fall of 1941.

PENNSYLVANIA

New Health Officers.—Dr. Anthony J. Sparta, Easton, has been appointed medical director of Northampton County, succeeding Dr. Frank J. Conahan, Bethlehem.—Dr. James E. Peterman, Cherry Tree, has been appointed district medical director of Indiana, Armstrong and Jefferson counties.—Dr. Matthew P. Ward, Brownsville, has been made medical director of Fayette County to succeed Dr. J. Glenn Hemington, Uniontown.—Dr. John L. Bond, Lehigh, has been appointed medical director of Carbon County.

UTAH

Study of Industrial Disease.—The state board of health with the collaboration of the U. S. Public Health Service and the Utah Industrial Commission has begun a statewide study of occupational disease under the direction of Dr. John L. Jones, Salt Lake City, state health commissioner, who has been granted a two year leave of absence for the work. The state legislature has appropriated \$25,000, which will be used for the conduct of the study with a view to developing a permanent occupational disease service in the state. The federal public health service will participate in the first six months of the investigation, the major problems of which will be exposure to silicious dusts and dusts in bituminous coal mines, lead and other metallic dusts and fumes and certain gases. In the latter part of the two years set apart for the study, health hazards in other industries will be investigated. In the major industries about 3,000 of the 16,000 workers employed and their working environments are to be studied.

WASHINGTON

Personal.—Dr. Kenneth M. Soderstrom, Seattle, was recently appointed to the staff of the division of epidemiology in the state department of health in charge of tuberculosis control, a newly created position.

WEST VIRGINIA

Personal.—Dr. William Price Bittinger, Summerlee, has been appointed a member of the Public Health Council by Governor Holt. He succeeds the late Dr. Samuel W. Price, Scarbro.—Dr. Harry A. Smith, Wheeling, has been appointed health officer of Wheeling and Ohio County.—Dr. John B. Hozier of the U. S. Public Health Service has been detailed to the West Virginia State Department of Health at Charleston as acting director of the bureau of venereal disease in the absence of Dr. Charles N. Scott, who will spend a year at Johns Hopkins University.

WISCONSIN

State Medical Meeting at Milwaukee.—The ninety-eighth annual meeting of the State Medical Society of Wisconsin will be held in Milwaukee September 13-15 under the presidency of Dr. Raymond G. Arveson, Frederic. Guest speakers who will address general sessions are:
Dr. Rock Sleyster, Wauwatosa, President of the American Medical Association, The Sick Man as a Person.
Dr. Arthur W. Erskine, Cedar Rapids, Iowa, Modern X-Ray Therapy.
Dr. Edward L. Tuohy, Duluth, Minn., The Relation of Alcohol to Liver Damage.
Dr. Alexander E. Brown, Rochester, Minn., Sulfanilamide, Neoprontosil and Sulfapyridine and Their Clinical Applications.
Dr. Harry E. Mock, Chicago, Abdominal Pain and Appendicitis.
Dr. Gilbert J. Thomas, Minneapolis, Hematuria.
Dr. Arthur H. Curtis, Chicago, Management of Carcinoma of the Cervix.
Dr. August A. Werner, St. Louis, The Sex Hormones.
Dr. Thomas J. Dry, Rochester, Minn., Pulmonary Hypertension and Right Heart Failure.
Dr. Willard D. White, Minneapolis, Operative Treatment of Fractures of the Neck of the Femur.

Several guests will address section meetings as follows:
Dr. Samuel J. Pearlman, Chicago, Acute Cervical Cellulitis.
Dr. Arthur W. Proetz, St. Louis, Regeneration of the Ciliated Nasal Epithelium.
Dr. Harry S. Gradle, Chicago, Errors in Glaucoma That I Have Made and That I Have Seen.
Dr. Henry P. Wagener, Rochester, Minn., Significance of Retinal Vascular Lesions.
Dr. Albert H. Montgomery, Chicago, Some Congenital Abnormalities of Infants and Their Treatment.
Dr. Tuohy, Duluth, An Adequate Dietary in Later Life.
Dr. Curtis, Chicago, Special Features in the Female Pelvic Viscera.
Dr. Charles F. Read, superintendent of the Elgin State Hospital, Elgin, Ill., will deliver the Rogers Memorial Lecture on "Mental Medicine in 1939." Another feature will be a symposium on "Low Back Pain" in which the speakers will be Drs. Edwin W. Ryerson, George H. Coleman, Harry Culver, Eugene Cary, all of Chicago, and Eben J. Carey, Milwaukee. Several of the guest speakers and Wisconsin physicians will conduct round table luncheon discussions, and there will be a smoker Wednesday evening at the Schroeder with Dr. William A. O'Brien, Minneapolis, as the speaker.

GENERAL

International Cancer Congress.—Dr. Francis Carter Wood, New York, president of the third International Cancer Congress to be held in Atlantic City, N. J., September 11-15, has telegraphed THE JOURNAL that, despite the inability of some foreign guests to attend, the congress will be held as planned. The meetings will be at Haddon Hall.

Fraudulent Magazine Solicitor.—A physician of Albany, N. Y., reports a swindler who solicits magazine subscriptions from physicians. Using the name H. E. Smith or H. E. Stanton, this man claims to be a representative of the Times Sales Company, Chicago. He carries forged credentials and cashes checks with forged names, it is said. The Times Sales Company states that reports have been received of "Smith's" activities from various parts of the country and that the firm has not been able to identify him.

Directory of Specialists.—The Advisory Board for Medical Specialties announces that a "Directory of Medical Specialists" is to be published in December, listing the more than 16,000 specialists who have been certified by the special board. There will be three sections: a description of the special board, a list of the diplomates of all boards, and an alphabetical list of the diplomates of all boards. It is expected that the directory will be issued every two years. Subscriptions at \$3.50 the copy may be made through the Columbia Press, 2960 Broadway, New York, or through the office of the director, Dr. Paul Titus, 1015 Highland Building, Pittsburgh.

Dr. Icie Macy-Hoobler Wins Borden Award.—At the recent annual meeting of the American Home Economics Association in San Antonio, Texas, Icie Macy-Hoobler, Ph.D., director of the research laboratory of the Children's Fund of Michigan, Detroit, was presented with the 1939 gold medal and the \$1,000 prize of the Borden Company for "outstanding research achievement in applied nutrition." Dr. Macy-Hoobler took her degree of doctor of philosophy from Yale in 1920. She has served as assistant in chemistry at the University of Colorado, assistant biochemist in Western Pennsylvania Hospital, Pittsburgh; instructor in the University of California and in charge of nutrition in the Merrill-Palmer School, Detroit. She has been with the Children's Fund for a number of years.

Panamerican Congress on the Child.—The eighth Panamerican Congress on the Child will be held in San Jose, Costa Rica, October 12-19. In addition to plenary sessions,

there will be meetings of six sections: medical pediatrics, surgical pediatrics, child hygiene and eugenics, education, social assistance and legislation. Medical subjects on the program for discussion include: infantile avitaminosis in the tropics; blood transfusion in pediatrics; surgical treatment of Pott's disease in childhood; diagnosis and treatment of osteomyelitis; control of tuberculosis. In addition to the congress program there will be exhibits on social hygiene, maternal and infant welfare and all branches of science, commerce and art bearing on the child. Dr. Alfonso Acosta Guzman is president of the organizing committee for the congress and Dr. Mario Lujan Fernandez, secretary.

Biologic Photographers to Meet.—The eighth annual convention of the Biological Photographic Association will be held at the Mellon Institute for Industrial Research, Pittsburgh, September 14-16, under the presidency of Mr. Louis Schmidt, Rockefeller Institute for Medical Research, New York. Among the features will be a special session on the uses of scientific photography with the following speakers: Mr. Robert Cook, Washington, D. C., editor of the *Journal of Heredity*; Mr. Watson Davis, director of Science Service, Washington; Mr. David Dietz, science editor, Scripps-Howard newspapers, Cleveland, and Capt. John Bradley, chief of the division of motion pictures and sound recordings, The National Archives, Washington. Mr. Ralph Creer, Hines, Ill., will preside at a discussion of "The Scientific Photographic Department"; Mr. Leonard Julin, Mayo Clinic, Rochester, Minn., one on "Surgical and Clinical Photography" and Mr. Leo Masopust, Marquette University, Milwaukee, "Photography with the Microscope."

American Roentgen Ray Society.—The fortieth annual session of the American Roentgen Ray Society will be held in Chicago at the Palmer House September 19-22, under the presidency of Dr. Edward L. Jenkinson, Chicago. The program includes the following speakers:

- Dr. James Ralston Kennedy Paterson, Manchester, England, The Radio-sensitive Tumors.
- Dr. Hermann Holthausen, Hamburg, Germany, Indication for the Duration of Irradiation in the Treatment of Cancer.
- Dr. Waltman Walters, Rochester, Minn., Surgical Treatment of Ulcerating Gastric Lesions.
- Dr. Clarence N. McPeak, Fitchburg, Mass., Syphilis of the Stomach.
- Dr. Barton R. Young, Philadelphia, Recent Advances in Roentgen Examination of the Neck; Planigraphy of the Larynx.
- Ansel B. Keys, Ph.D., Drs. Hymer L. Friedell and Leo G. Rigler, Minneapolis, A Method for the Measurement of the Valvular Efficiency of the Heart.
- Dr. Traian Leucutia, Detroit, Late Results in Supervoltage Roentgen Therapy.
- Dr. Philip Lewin, Chicago, The X-Ray Findings in Lower Back and Sciatic Pain.
- Drs. Karl Kornblum and Hobart A. Reimann, Philadelphia, Roentgenologic Aspects of an Epidemic of Acute Respiratory Tract Infection.
- Dr. Pedro L. Fariñas, Havana, Cuba, Recent Progress in the Bronchographic Diagnosis of Bronchogenic Carcinoma.
- Drs. John T. Farrell Jr., Martin J. Sokoloff, Philadelphia, Robert K. H. Charr, White Haven, Pa., Prognosis in Silicosis: Roentgenologic Study Based on 500 Cases.

Dr. James T. Case, Chicago, will deliver the Caldwell Lecture Tuesday evening September 19 on "Roentgenology of Pancreatic Disease." The afternoons will be devoted to instructional courses.

Eyesight Swindler Mandel Sentenced to Federal Penitentiary.—Ernest Mandel, whose name, variously spelled, has been mentioned in several items in *THE JOURNAL* as one of the eyesight swindlers who have extracted large sums of money from persons in many states, was convicted in the federal court in Baltimore July 13 and sentenced to five years in the federal penitentiary at Lewisburg, Pa., according to newspaper reports. Mandel pleaded guilty to the charge of having posed as a "government doctor" and having obtained \$1,450 from a woman in Frederick County (Md.) for a so-called operation on her eyes in 1936. He admitted, the *Baltimore Sun* said, that he had no medical or surgical training and that he used harmless eye washes, various lenses, the white of an egg and fish skin, the latter being shown to the patient as a cataract removed from the eye. He also said in court that he had made an income of between \$6,500 and \$7,500 a year for the past four years and that he had received as much as \$3,000 from one person. Mandel and an assistant, Lawrence F. Welch, were indicted last March and Mandel was apprehended in May by federal agents in New Orleans, which he said had been his home for twenty-three years. Welch is still being sought. *THE JOURNAL*, March 17, 1934, page 849, reported that a man giving the name of E. J. Mandell or Mendell had been arrested in Kentucky for working his racket in company with one Bernstein. At that time the men were released on promise to repay \$300 they had taken from a Kentucky victim. In 1937 one Samuel Birnstein of New Orleans was fined \$600

and sentenced to two years in the state house of correction in Massachusetts following his conviction on an "eye racket" charge. In the same year, a federal court in Milwaukee fined him \$1,000 and sentenced him to two years in federal prison after he had served the Massachusetts sentence (*THE JOURNAL*, May 1, 1937, p. 1547).

Congress on Microbiology.—The third International Congress of Microbiology will be held at the Waldorf-Astoria, New York, September 2-9 under the presidency of Dr. Thomas M. Rivers, New York. Sessions will begin Monday. There will be three general sessions with the following speakers, among others:

- Dr. A. J. Kluyver, Delft, Microbial Metabolism and Its Significance to the Microbiologist.
- Dr. Paul G. Fildes, London, Nutrition of Bacteria.
- Dr. C. Levaditi, Paris, Chemotherapy of Infectious Diseases.
- Dr. Alberto Missiroli, Rome, Practical Developments Resulting from the New Researches on Plasmodia.
- Wendell M. Stanley, Ph.D., Princeton, N. J., Properties of Viruses.

There will be nine sections: general biology, variation and taxonomy; general biology, microbiologic chemistry and physiology; viruses and viral diseases; rickettsiae and rickettsial diseases; protozoology and parasitology; fungi and fungous diseases; medical and veterinary bacteriology; agricultural and industrial microbiology, and immunology. Among numerous discussions will be two sessions of the section on medical and veterinary bacteriology on "Chemotherapy of Bacterial Infections." Among the speakers announced on the program are Drs. Gerhard Domagk, Wuppertal-Elberfeld, Germany; Leonard Colebrook and A. T. Fuller, Ph.D., London; Konrad Birkhaug, Bergen, Norway; Ralph R. Mellon, Arthur P. Locke, Ph.D., and Lawrence E. Shinn, Ph.D., Pittsburgh; Drs. Sara E. Branham, Sanford M. Rosenthal and Hugo Bauer, Washington, D. C.; Perrin H. Long and Eleanor A. Bliss, Sc.D., Baltimore. Hundreds of papers will be delivered in other sections, including symposiums on air-borne infections; encephalitis and choriomeningitis; relation of filtrable viruses to tumor formation; poliomyelitis, tuberculosis, diphtheria, rabies, yellow fever, influenza and other respiratory diseases; the pneumococcus, the streptococcus, tissue immunity and allergy.

CANADA

International Hospital Meeting.—The sixth biennial congress of the International Hospital Association will be held in Toronto September 19-23 at the Royal York Hotel. There will be five plenary sessions and about forty study committees will meet individually and then will present final reports at the last plenary session. Dr. Malcolm T. MacEachern, Chicago, president of the association, will deliver his official address at the formal opening meeting Tuesday evening September 19 on "World Unity in Relief of Suffering." Subjects to be discussed at the second, third and fourth plenary sessions are: "Worldwide Advances in Hospital Construction"; "The Place of the Hospital in the Community" and "Hospital Organization and Management." Friday evening September 22 there will be a "Health Conservation Meeting" with the following speakers:

- Dr. René Sand, Brussels, secretary-general, Belgian ministry of health, Health and Human Progress.
- Dr. William McAdam Eccles, London, The Voluntary Hospital.
- Dr. Hans Frey, Bern, Switzerland, The Role of the Hospital in Health Conservation.
- Dr. Frederick W. Routley, National Commissioner, Canadian Red Cross, Toronto, A Health Program for Canada.
- Rt. Rev. Monsignor Maurice F. Griffin, Cleveland, Voluntary and State Cooperation in Health Conservation.

Meetings of other hospital groups will also be held in Toronto on the following dates: Canadian Hospital Council, Dr. George F. Stephens, Winnipeg, Man., president, September 21-22; Protestant Hospital Association, Mr. Bryce L. Twitty, Dallas, Texas, president, September 24-26; American College of Hospital Administrators, Dr. Robin C. Buerki, Chicago, president, September 24-25, and the American Hospital Association and allied groups, Dr. George Harvey Agnew, Toronto, president, September 25-29.

FOREIGN

International Congress for Radiology.—The sixth International Congress for Radiology will be held in Berlin July 31 to August 4, 1940. In addition to general sessions, sectional meetings will be held in the following divisions: roentgen diagnosis, radiotherapy, radiobiology, physics and technic, electroluminescence and light. Those who wish to present papers should notify the president by December 15 and abstracts should be in the hands of the secretary-general by Feb. 1, 1940. The president is Dr. Holthausen, Goernestrasse 29, Hamburg 20, and the secretary-general, Dr. Willy Baensch, Liebigstrasse 20, Leipzig 1.

John Mellanby

Prof. John Mellanby, F.R.S., eminent physiologist, has died at the age of 61 years. He belonged to a distinguished family, his elder brother being Prof. Alexander Mellanby of Glasgow and his younger brother Sir Edward Mellanby, secretary of the Medical Research Council. He studied biology at Cambridge, where he took first class honors in the natural science tripos. In 1902 he inaugurated the physiologic department of the new research laboratories of Burroughs, Wellcome & Co., where he did original work on the globulins. After three years he entered Manchester University as a medical student and in 1907 took the M.D. of Cambridge. He passed the next two years at the laboratory of that university, where he did his well known work on blood coagulation. In 1909, at the age of 31, he was appointed head of the physiologic department of St. Thomas's Hospital, where he remained for twenty-five years, becoming a professor of London University in 1920. In 1936 he succeeded Sherrington as professor of physiology at Oxford. His original work covered a wide field and at first attracted little notice but later was recognized as classic. In addition to his researches on the globulins and blood coagulation, already mentioned, he collaborated with Wooley in a study of the enzymes of the pancreas. This led him to demonstrate the particulate absorption of unhydrolyzed fat through the agency of the bile salts. He distinguished the parts played by the vagus and secretin in pancreatic secretion and refuted the teaching that secretin was produced by the activation of prosecretin by hydrochloric acid. He showed that secretin was present as such in the intestinal mucosa and that it was liberated into the blood stream by the bile salts. His researches on the action of the bladder, the relation of the nervous system to the blood sugar and glycosuria, the nature of enzyme action, anoxia, carbon dioxide carriage, carbon monoxide poisoning and snake venoms are well known. But of all his work that on blood coagulation was perhaps the most important. He isolated pure thrombase and prothrombase and showed that the latter was not related to the platelets but was a plasma protein, forming a complex with fibrinogen. A master of exposition, his analysis of the most complicated physiologic processes was a delight to his students.

Drugs of Sulfanilamide Group in Tropical Medicine

At the Royal Society of Tropical Medicine and Hygiene, a discussion on the action of sulfanilamide and its derivatives in tropical diseases was opened by Dr. G. A. H. Buttle, who said that many tropical diseases had been found to be benefited. Elephantoid fever with its accompanying lymphangitis was rapidly controlled, owing to the action on the secondary streptococcal infection. In malaria *Plasmodium knowlesi* infection of monkeys was rapidly cured, but *P. relictum* in birds and *P. falciparum*, *P. vivax* and *P. malariae* in man were much less susceptible. The drugs, however, appeared to act as a true causal prophylactic in *P. falciparum* in man and treatment at the time of the mosquito bites prevented infection. They were the only known drugs with this action. In typhoid some benefit might be expected from sulfanilamide and sulfapyridine in the first week of the disease but later was much more doubtful. In infection with *Brucella abortus* and *melitensis* good results were reported but were perhaps not so striking as in streptococcal, meningococcal and pneumococcal infections. In plague, experiments with sulfapyridine had given remarkable results, but there was little published work on its action in bubonic plague in man. The only virus conditions

directly influenced were lymphogranuloma and trachoma. In the former sulfanilamide was effective, while in the latter the corneal condition improved much more than the conjunctival. In smallpox pustulation was prevented.

Col. J. A. Sinton's experience was limited to experiments with cases of induced malaria. In man sulfanilamide compounds had not proved as effective as the cinchona alkaloids and atabrine. With the Rumanian strain of *Plasmodium falciparum* the febrile stage was cut short, but relapses tended to occur.

Dr. Philip Manson-Bahr said that the problem was no longer when to administer sulfanilamides but when not to do so. He had been impressed by the results in pneumonia, genito-urinary infections in tropical patients, tonsillitis, sinusitis and middle ear trouble, but in venereal lymphogranuloma and certain chronic ulcerations they were not so satisfactory. Thus in two cases of tropical ulcer and in one of ulcerating granuloma of the pudenda there was no effect. Two seamen from the tropics, in whom he diagnosed on clinical grounds infective endocarditis, responded dramatically to intravenous prontosil soluble. In abortus fever prontosil and soluseptasine shortened the fever, but relapses occurred.

Dr. Dyce Sharp had seen miraculous results in puerperal fever and in tetanus in West Africa. His last five tetanus patients recovered under drugs of the sulfanilamide group. When the patient could swallow he gave them by the mouth; otherwise, intravenously every four hours.

Blood Transfusion Week

Thanks to the generosity of private persons a center of hematologic research and blood transfusion has been organized in Paris. This center has been able for two years to effect more than 53,000 transfusions in the hospital centers in the Paris area. There was need of establishing other centers of this kind in the provinces. For this reason a blood transfusion week lasting three days was instituted, a kind of symposium uniting, under the leadership and even the presidency of the head of the state, all the agencies and specialists involved. Many physicians and university teachers came from outside Paris and from the French colonies. The first session of the week was devoted to regional centers. The second day, under the presidency of the minister of war, army blood transfusion was discussed, with emphasis on blood conservation and the lessons taught by the Spanish civil war. On the third day, deliberation centered on means and ways of organizing internationally blood transfusion research centers, and the foundation of an international society for blood transfusion research was voted.

Scarification Method of Vaccination with BCG

Weill-Hallé has been trying out for many years different methods of utilizing the BCG vaccine. He prefers at present subcutaneous injections of 0.05 mg. He also employs scarification. He applies three drops of the solution of 0.005 Gm. to 1 cc. on the skin of the arm, 2 or 3 cm. apart and across these drops makes a crosswise scarification. A gauze compress and tape are applied to the small scarified wound. The penetration of the germ along the course of the lancet is thus prolonged by the presence of the vaccine. The small scarification disappears within two or three days. Then between the fifteenth and twenty-fifth days, according to whether revaccination or first vaccination is in order, vaccinal traces reappear and a very small scar forms, which lasts for some weeks before complete healing. However, from the time of the appearance of the local reaction, Pirquet's test is slightly positive. Scari-

fication, which has the advantage of being very simple, seems to induce susceptibility at all age levels, a susceptibility that attests the acquisition of resistance to virulent infection. The only objection to it is its quantitative inaccuracy. It therefore ought to be supplemented by observing the allergic conditions by means of repeated cutaneous tests. Lesné, who made a supplementary report at the Academy of Medicine, thinks that the most practical form of cutaneous tests is the percutaneous test. It is much more easily read, according to his account, than the cutaneous test when the reaction is weak.

Medical Meetings at Brussels

The Brussels meetings were really held at Liège because of the dedication of the new large canal crossing Belgium from east to west and of the water exposition taking place this year in this city. Several medical societies participated, notably the Belgian Society of Surgeons, the Belgian Society of Orthopedists, in which Verbrugge read an extensively documented paper on osteosynthesis in children, and the Belgian Society of Gastro-Enterology, in which Bottin reported on water metabolism in surgical disorders of the digestive canal and Delrez on the early diagnosis and surgical treatment of carcinomas of the colon. About 1,300 physicians representing thirty different nations made their contributions. Professor Mauriac, dean of the Faculty of Medicine of Bordeaux, who was the presiding officer of the medical sessions, read a paper with the significant title "The Physician as Arbiter and Defender Midway Between Society and the Harassed Individual." It was a splendid and eloquently delivered clarification of medical principles in the loftiest sense of the word and at the same time an expression of a physician's faith in an idealism compatible with the present day requirements of medical science and the medical profession.

BERLIN

(From Our Regular Correspondent)

July 24, 1939.

Increase of Epidemic Cerebrospinal Meningitis

According to recent official calculations, the incidence of epidemic meningitis has of late shown an increase. Until the latter part of December 1938 the number of cases reported weekly since 1923 for the German reich, exclusive of Austria and Sudetenland, did not exceed fifty-three. The incidence rate, therefore, for a long number of years was maintained at the same relatively low level. In the last week of December 1938, however, sixty-one cases were reported for the first time. In the first eleven weeks of 1939 the total number for Germany, exclusive of the regions added by conquest, rose to 1,355; inclusive of these regions, to 1,576; ten administrative districts were especially endangered (the Trier district in the Rhineland most of all with two others similarly so), showing a rate of 8.71 per hundred thousand inhabitants within the aforementioned eleven weeks. Berlin ranks tenth in the scale of frequency with 1.93 per hundred thousand. In the endangered regions the greatest frequency occurs at about the eighth week but evolution is not concluded by the eleventh week. Nothing further is known. The central department of public health has issued another memorandum to physicians with suggestions for combating the disease.

Periodicity in Epidemics of Influenza

H. J. Juszat discusses in the *Zeitschrift für Hygiene* the periodicity of epidemic influenza and the possibility of an epidemiologic prognosis. Such periodicity can apply only to the rhythmic behavior of the individual epidemics. The rhythmic periods observed in epidemic influenza within the last 200 years fluctuate in length, similar to the rhythmic occurrences in climatic studies extending over a long period. Because of

this varying behavior the prerequisites for predicting future epidemics of influenza are made difficult. For the statements of Wolter that the rhythm of an epidemic occurrence of influenza follows the fluctuations between predominantly moist and dry years, no proof can be obtained from a survey of epidemics of the last two centuries. Hence the prediction of a future epidemic on the basis of Wolter's views is not possible. Only the prognosis of the last two epidemics (1932-1933 and 1936-1937) was verified by facts. This prognosis was made in 1927 and was based on the hypothesis of the coincidence of the rhythmic appearance of influenza epidemics with the cycle of solar activity noted in each case. According to this hypothesis the next large epidemic in all probability is to be expected in 1948-1949.

Plastic Surgery

Professor Axhausen, a Berlin surgeon, recently discussed before the local society of surgeons several basic problems of plastic surgery. Accidents leading to the loss of the skin of the face have become more numerous, especially those caused by crashing planes. The face of the flier is the only part of the body exposed and easily injured when the plane catches fire. The whole face may then become a single granulating surface with progressive scar formations eventuating in ectropion. Food ingestion is interfered with. The wounded can endure their condition only if the wounds are constantly covered with salve-anointed bandages. In accidents of this kind plastic replacement of the skin of the face becomes a vital question. An improvement, cosmetically as well as functionally, was achieved by means of bandages supplied with handles. Axhausen further discusses the operative correction of the lip with unfavorable healing. He recommended, in most cases, excision of the scars and new plastic treatment. In other cases a correction was sufficient.

Study of Canned Meats

Dr. Clarenburg, a bacteriologist, and Dr. Zwart, public health veterinary inspector, undertook an investigation of the choice and preparation of canned meats. In the process of meat sterilization a certain time must elapse before the temperature of the inside of the container approximates that of the outside. Experiments have been made and measurements of the temperature in different autoclaves during sterilization have been studied. The fact that the containers had been subjected for a definite time to a definite temperature gives no assurance of good quality. The construction of sterilizers and the processes of work followed are of great importance. As to what constitutes good quality, emphasis must be laid on the fact that no defects of color, taste, smell or consistency be found and on the absence of pathogenic germs or harmful elements. As to weight, it is necessary to let the containers remain from three to seven days in a temperature of 98.6 F., after which time no interior or exterior changes should be observed. Sterilization of all meats cannot be required because the quality of the different products does not permit it. Eighty-six specimens of twenty different kinds of meat were observed after the incubation temperature. Fifty-eight of these seemed sterilized and nine bulged and were spoiled by bacteria, while nineteen containers showing the presence of germs did not seem to have undergone any observable change. All specimens of ham and lard seemed to contain germs. It was therefore impossible in practice to obtain sufficient heat to guarantee sterilization. It was desirable that there be noted on the containers whether the contents were sterilized or not, as well as the date of canning. For this purpose an understanding with the manufacturer is to be encouraged.

Child Welfare Congress in Utrecht

The third child welfare congress, just held in Utrecht, had Princess Juliana among the honored guests. Romme, minister of social affairs, stressed the progress of child welfare in recent years. N. Knapper said that a course for mothers without a service offering them practical advice was not sufficient. Dr. Koenen was of the opinion that joint bureaus for infants and young children should be disapproved of for hygienic reasons. Dr. Gorter spoke of infant mortality and children's diseases and their decrease as a result of the progress of hygiene. Van der Zande discussed the physical culture of children. A film is planned on this subject. Mrs. Nanninga-Boon stressed the need of cultivating self confidence in deaf-mutes and of removing the inferiority complex. Members of the congress were received at the Utrecht city hall by the mayor, who took occasion to point out what the city had already achieved in the field of the education of the young.

Bovine Type of Human Tuberculosis

Dr. Charlotte Ruys has studied the controversial subject of the significance of bovine infection in the transmission of tuberculosis in Amsterdam's health laboratories. A considerable percentage of tuberculosis among children is to be attributed to bovine infection. Pulmonary tuberculosis of adults in cities is almost always due to human infection. In the country it is not unusual to see the bovine type appear in adults. Infant tuberculosis caused by the bovine type of infection in the majority of cases is acquired by way of the alimentary canal. In adults, pulmonary tuberculosis of this type is perhaps partially acquired through the air. For the other forms of tuberculosis it is probable that the digestive apparatus has significance only so far as it paves the way for infection.

Silicosis

The health services instituted an inquiry in 1938 to determine the presence of silicosis among sand workers. Nearly 250 workers were examined, of whom more than half had worked less than three years at the occupation; 48 per cent of these workers worked from one to eight hours weekly, 17 per cent from one to three days weekly; the remaining 35 per cent gave their full time to it. Of the total number examined, 20 per cent showed clinical signs of pulmonary trouble. In 8 per cent the diagnosis of silicosis had been clinically conducted. Ninety-four patients were roentgenographed. It was discovered that thirty-three definitely had silicosis and eight had tuberculous silicosis. In twelve, silicosis was doubtful and one had pulmonary tuberculosis. This investigation clearly demonstrates the insufficiency of the precautionary measures taken by the workers.

Bakers' Eczema

In the *Nederlandsch tijdschrift voor geneseskunde* Drs. J. K. Prakken and C. Postma emphasize the distinction between bakers' eczema and other forms. This occupational disease is found on the hands and forearms, appearing or showing exacerbation when dough is handled and disappearing when manipulation with dough ceases. It has been attributed to chemicals used in whitening flour, especially to ammonium persulfate ($(\text{NH}_4)_2\text{S}_2\text{O}_8$). To shed light on this problem, the authors employed cloths wet with ammonium persulfate. Small strips of cloth were soaked in a solution of from 1 to 5 per cent as well as in a solution of 1:1,000 (concentration at which ammonium persulfate would be found in flour). These pads were placed on the back and removed after twenty-four hours. A positive reaction consisted in the appearance of a papulovesicular eruption within three to seven days. These tests were positive in fourteen of fifteen persons suffering from bakers' disease.

BUDAPEST

(From Our Regular Correspondent)

The Code of Ethics in Hungary

Since the Hungarian National Medical Chamber was established, the management has formulated rules relating to medical practice. The draft of these regulations, which has just been completed, makes a volume of 300 pages, divided into eleven chapters. The general rules deal with consultation practice, the relation of physicians to patients and to fellow practitioners, abortion and birth control, free treatment, the problem of professional secrecy, and the relation of physicians to medical societies. The whole draft is pervaded by the point of view of preserving medical dignity. That part of the medical society which places the professional point of view above actual daily politics is embittered lest the fierce disputes about publicity undermine the prestige of the profession and not only lead to the decline of the social standing of the physician but also render impossible the true relation between physician and patient. The excessive publicity of some physicians in the daily press caused the insertion of regulations which acknowledged that in many instances their articles were useful to the public but in many instances they could be made more consistent with medical ethics. Therefore the by-laws forbid most rigorously placing advertisements in daily papers. As to writing articles, there is no categorical prohibition but articles written by medical men must not have a flavor of advertisement. It is yet uncertain what point of view will be taken with respect to abortion. The draft states that members of the medical chambers must not demand fees lower than fixed by the chamber. The minimum fees for consultations, calls, operations and, in general, all medical services will be fixed at a later date.

The Hungarian Law on Jewish Physicians

The main motive of the elaboration of the Jewish law was that Jewish physicians occupy most medical public and private positions, thus depriving gentile physicians. As against this statement the official statistics relating to the year 1930 has just been published, since which time no Jewish physicians, with few exceptions, have received positions. According to these statistics there were 3,633 medical positions occupied by gentiles and only 701 by Jews. According to the instructions, the Medical Chambers have to prepare separate lists of physicians who are in public service or in institutes established by law, and of physicians in private practice between which groups a proportion of 80:20 shall be preserved. The proportion of 16.1 per cent, allotted in 1930, does not now prevail and it will decrease more and more. There is no instruction in the law as to what would happen if a Jewish physician in office should be pensioned and continue to deal with private patients; should he be placed in the group of unemployed doctors? This stipulation concerns young Jewish physicians graduating now, as until the time of the attainment of the 80:20 proportion only 5 per cent of Jewish physicians can be enlisted in the medical chamber. Another grievance is that, according to the law, in case of removal from one town to another a Jewish physician can be enlisted in the chamber of the new domicile only up to 5 per cent. If a Jewish physician residing in a provincial town should get a good position, say, in Budapest, he could get admission to the Budapest chamber only in accordance with the 5 per cent rate and might have to wait for years, in spite of the fact that he was already a member of a chamber.

The ninth paragraph of the by-laws prescribes that members coming under the 20 per cent group can be admitted as members of the chambers only in January and July. This means a disadvantage for young Jewish physicians, because they may be unable to begin practice for half a year.

OSLO

(From a Special Correspondent)

Aug. 1, 1939.

The Legalized Sterilization of Women

The facilities provided by law for the sterilization of women on certain indications have been abused at times. Since July 1, 1926, several scores of women have been sterilized at the Sauda Hospital, where the indications for this operation have been sociologic (dipsomania, disease or unemployment on the part of the husband) as well as medical. The medical indications have often been tuberculosis or heart disease. A follow-up study of the sixty-eight women sterilized at this hospital before July 1, 1938, has been undertaken by Dr. Bernhard Paus with the object of ascertaining the physical and mental reactions of these women after an interval long enough to allow of mature reflexion.

The ages of the patients ranged from 20 to 43. Among them they had undergone 275 confinements and forty-nine spontaneous abortions. In all but one case, in which prolapse of the uterus favored the vaginal operation, the abdominal route was chosen. The fallopian tubes were resected for a distance of 1 to 2 cm., and in as many as thirty-seven cases, minor cesarean sections were also performed. There were no deaths, but embolism occurred in two cases and thrombophlebitis in one case. None of the sixty-one women who were reexamined in the course of the follow-up study had become pregnant after the operation. But the failures, or at least the disappointments from the psychologic point of view, were numerous. Religious scruples or regrets were noted in seven cases, and in two cases the husbands had also become regretful, one because he had been "converted" in a religious sense, the other because the sexual activity of his wife had greatly been reduced since the operation. In several cases lassitude and disinclination for work appeared to be a sequel to the operation. Its implications and after-effects would therefore seem serious enough to deter both doctors and patients from any light-hearted acceptance of it.

Boeck's Sarcoid, or the Schaumann Syndrome

When the late Professor Boeck of Norway described a condition of the skin associated with his name, he probably failed to realize that this was merely the outward sign of a most serious general disease. And it was not till 1914, when Schaumann published his important study of what he called lymphogranuloma benignum, that all or nearly all the manifestations of this ailment were linked up in a comprehensive syndrome. But it still bears the name of Boeck's sarcoid even though the cutaneous manifestations of the disease would seem to be the exception rather than the rule. Visitors to the Rikshospital in Oslo should now have plenty of opportunity for studying this disease either in Professor Salvesen's or Professor Hanssen's department. This means that the disease is comparatively common, or is it that the recent revival in the interest taken in Boeck's sarcoid has led to a search for and combing out of these cases throughout the land with a view to their being admitted to the Rikshospital? Certain it is that Professor Salvesen's department has become the receptacle for quite a variety of ailments hitherto unknown or considered as very rare, and this is most useful for a hospital serving as a great teaching center. As for Professor Hanssen's department, one of his assistants, Dr. H. J. Ustvedt, recently published an account of twelve cases of Boeck's sarcoid. In his opinion the diagnosis must depend on a careful clinical assessment of all the evidence, for there is not one pathognomonic sign unless it be the skin lesion, which, by the way, was found in only two of his twelve cases. The other

manifestations—hilus adenitis, swelling of the salivary glands, iridocyclitis, osteitis multiplex cystoides, fever and certain radiologic opacities in the lungs—may, if combined in one and the same case, form a quite definite picture warranting the diagnosis of Boeck's sarcoid. But the trouble is that the diagnosis is seldom anything more than a probable diagnosis, the probability dwindling as the number of the more or less characteristic features of this syndrome are conspicuous by their absence. There is a corresponding vagueness with regard to etiology, and there are still doubts as to the part played by the tubercle bacillus.

The Chemotherapy of Pneumonia

The serum treatment of pneumonia has never enjoyed much of a vogue in Norway, where the distances between the patient and a well equipped laboratory are often great. But the modern chemotherapy of pneumonia is already so universally accepted that not to give sulfanilamide or sulfapyridine or some other member of the same group would now be considered unwarrantable. One drawback to this wholesale unanimity is the lack of control cases. To give sulfapyridine only to every other patient admitted to the hospital for pneumonia for the sake of comparison would be condemned as sacrificing the individual on the altar of science. Thanks to this state of affairs, little difficulty has been experienced by Dr. Römcke and Dr. Vogt in collecting from various hospitals the records of 342 patients who suffered from croupous or atypical pneumonia during the brief period between the middle of October 1938 and May 1, 1939. They discarded all the cases in which the pneumonia was secondary to an operation or other ailment, in which the diagnosis of pneumonia was in doubt, or improvement had begun before the drug was given, or its dosage was under 3 Gm. for adults, or empyema complicated the issue on the patient's admission to hospital, or when death occurred within twenty-four hours of such admission. They found that among their 342 more or less uncomplicated cases there were only twenty deaths, a mortality of 5.8 per cent. Going back to the period 1928-1938 in search of controls, they found that the mortality from pneumonia in this period ranged from 20.5 to 35.2 per cent. As for the ill effects of sulfapyridine, the worst would seem to be granulocytopenia, a serious case of which, ultimately ending in recovery, has had to be recorded.

Marriages

- ROBERT GLENN THOMPSON, Three Churches, W. Va., to Miss Marian Brownlee Hayes of Rock Hill, S. C., June 29.
LAWRENCE H. MILLS, Clarksburg, W. Va., to Miss Mildred Gertrude Young of New Martinsville, July 7.
ALTON GRADY BROWN, Rock Hill, S. C., to Miss Nellie Claire Sanders of Charleston, June 2.
HERMAN C. SCHMALLENBERG, New London, Wis., to Miss Dorothy Ehleke of Appleton, June 25.
ROBERT S. GEARHART, Madison, Wis., to Miss Dorothea Rehder of Lincoln, Iowa, July 22.
RALPH C. LAKE, Georgetown, Ky., to Miss Frances Blanche Binford in Springfield, July 5.
WESLEY C. MINZEL, Colville, Wash., to Miss Meredith Hickman in Spokane, June 1.
ROBERT P. KEISER, Miami, Fla., to Miss Alice Bidlingmaier of Hollywood, July 1.
ERVIN HANSHER to Miss Harriet E. Kesselman, both of Milwaukee, June 25.
CLARENCE M. STRAND, Westby, Wis., to Miss Eunice Lien of Rio, June 17.
DAVID M. REGAN to Miss Marion Martin, both of Berlin, Wis., July 11.

Deaths

Robert Stevenson Macdonald, Plattsburg, N. Y.; Cornell University Medical College, New York, 1902; member of the Medical Society of the State of New York; fellow of the American College of Surgeons; attending surgeon to the Champlain Valley Hospital; consulting surgeon to the Alice Hyde Memorial Hospital, Malone; General Hospital, Saranac Lake; Lake Placid (N. Y.) General Hospital; Clinton Prison Tuberculosis Hospital, Dannemora, and the Mercy Hospital, Tupper Lake; aged 62; died, June 4, near St. Alexis des Monts, Que., Canada.

Roy Richard Jones Ⓢ Passed Assistant Surgeon, U. S. Public Health Service, Washington, D. C.; State University of Iowa College of Medicine, Iowa City, 1919; from November 1935 to March 1938 he was detailed as medical adviser to the Division of Labor Standards, United States Department of Labor; secretary of the Committee on Medical Control of Silicosis, National Silicosis Conference; aged 48; died, June 13, at the Dr. W. H. Groves Latter-Day Saints Hospital, Salt Lake City, of complications following an operation for appendicitis.

Mary Elizabeth Botsford, San Francisco; University of California Medical Department, San Francisco, 1896; member of the California Medical Association; past president of the Associated Anesthetists of the United States and Canada; clinical professor of anesthetics emeritus at her alma mater; served as contract surgeon in the M. C., U. S. Army, during the World War; formerly on the staffs of the University of California and Children's hospitals; aged 74; died, June 18.

Jeremiah Sweetser Ferguson, Malba, N. Y.; University of the City of New York Medical Department, New York, 1892; assistant professor of histology, Cornell University Medical College, New York, 1908-1913, and for many years secretary of the faculty; on the staffs of the Gouverneur Hospital and the Willard Parker Hospital; author of a textbook on "Normal Histology and Microscopical Anatomy" published in 1905; aged 68; died, June 30, in the New York Hospital.

Claude Graham Hoffman, Louisville, Ky.; University of Louisville Medical Department, 1901; member of the American Urological Association; fellow of the American College of Surgeons; formerly associate in the department of urology at his alma mater; on the staffs of the Jewish, Children's Free and Louisville City hospitals, Norton Memorial Infirmary and the Kentucky Baptist Hospital; aged 59; died suddenly, June 24, of cerebral hemorrhage.

George Frederick Goodfellow Ⓢ Saratoga Springs, N. Y.; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1919; fellow of the American College of Surgeons; served in the Canadian Army during the World War; on the staffs of the Saratoga Hospital, Saratoga Springs, and the Benedict Memorial Hospital, Ballston Spa; aged 49; died, June 2, in the General Hospital, Kingston, Ont., Canada, of coronary thrombosis.

William V. Laws Ⓢ Hot Springs National Park, Ark.; Kentucky School of Medicine, Louisville, 1893; Medico-Chirurgical College of Philadelphia, 1900; member of the House of Delegates of the American Medical Association, 1913-1914; fellow of the American College of Surgeons; member of the American Urological Association; medical director of the Ozark Sanatorium; aged 73; died, June 9, of chronic myocarditis and nephritis.

Robert Wayne Harris, New Albany, Ind.; Hospital College of Medicine, Louisville, Ky., 1884; member of the Indiana State Medical Association; past president of the Floyd County Medical Society; bank president; formerly member of the city council and member of the city board of school trustees; on the staff of St. Edward's Hospital; aged 78; died, June 8, of coronary occlusion and chronic hypertension.

George Luther Davenport, North Chicago, Ill.; University of Illinois College of Medicine, Chicago, 1907; fellow of the American College of Surgeons; formerly assistant professor of surgery at his alma mater; at one time attending surgeon to the Michael Reese, Illinois Masonic and Cook County hospitals, Chicago; aged 57; died, June 29, in the Veterans Administration Facility of bronchopneumonia.

Herbert McKay Coulter, South Pasadena, Calif.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1903; member of the California Medical Association; formerly assistant professor of medicine (pediatrics) at the College of Medical Evangelists, Los Angeles; formerly physician inspector in the South Pasadena School System; aged 61; died, June 16.

Howard Merchant Francisco, Orofino, Idaho; University of Louisville (Ky.) School of Medicine, 1911; member of the American Psychiatric Association; served during the World War; on the staff of the State Hospital; formerly superintendent of the Eastern State Hospital, Lyons View, Tenn.; aged 58; died, June 2, of coronary disease.

Christopher H. Shearer Ⓢ Reading, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1897; fellow of the American College of Surgeons; served on the staff of the Reading Hospital in various capacities for many years; gynecologist to St. Joseph's Hospital, 1903-1910; aged 69; died recently of cerebral hemorrhage.

Thomas Waller Floyd, Peoria, Ill.; Kentucky School of Medicine, Louisville, 1897; member of the Illinois State Medical Society and the American Academy of Ophthalmology and Oto-Laryngology; served during the World War; on the staff of the Proctor Hospital; aged 66; died, June 5, at the Methodist Hospital of coronary occlusion.

David Wilson Smouse, Los Angeles; University of Maryland School of Medicine, Baltimore, 1876; member of the Iowa State Medical Society; past president of the Polk County (Iowa) Medical Society; formerly a practitioner in Des Moines, Iowa; in 1931 founded a school for handicapped children; aged 85; died, July 2, of arteriosclerosis.

Seymour Archibald, Edmonton, Alta., Canada; Bellevue Hospital Medical College, New York, 1897; district medical officer for the Canadian Pacific Railway for many years and chief medical officer of the Northern Alberta Railways; served with the Canadian Army Medical Corps during the World War; aged 63; died, May 5.

Harlan Horney, San Angelo, Texas; Chicago Homeopathic Medical College, 1895; Southwestern University Medical College, Dallas, 1904; member of the State Medical Association of Texas; served during the World War; formerly on the staff of the Shannon West Texas Memorial Hospital; aged 69; died, June 21.

Aldege Ethier, Montreal, Que., Canada; School of Medicine and Surgery of Montreal, Faculty of Medicine of the University of Laval at Montreal, 1892; professor of clinical gynecology at the University of Montreal Faculty of Medicine; formerly on the staff of the L'Hopital Notre-Dame; aged 70; died, June 2.

Karla Pauline Hahn Ⓢ Cleveland; Christian-Albrechts-Universität Medizinische Fakultät, Kiel, Prussia, Germany, 1924; on the staffs of the Lutheran and Deaconess Evangelical hospitals; aged 44; died, June 12, in the Bedford (Ohio) Municipal Hospital of injuries received in an automobile accident.

Stanley McClure Deakin, Imola, Calif.; College of Physicians and Surgeons, medical department of the University of Southern California, Los Angeles, 1912; member of the California Medical Association; on the staff of the Napa State Hospital; aged 52; died, June 1, of coronary occlusion.

Garry Richman Burke Ⓢ Alameda, Calif.; University of Buffalo School of Medicine, 1918; fellow of the American College of Surgeons; on the staff of the Alameda Sanatorium; aged 43; died, June 19, in the Sonoma County Hospital, Santa Rosa, of injuries received in an automobile accident.

Isaac W. Lamm, Lucama, N. C.; University College of Medicine, Richmond, 1899; member of the Medical Society of the State of North Carolina; bank president; for many years member and chairman of the school board; aged 74; died, June 20, in a hospital at Wilson of coronary occlusion.

Arthur Hall Dundon Ⓢ North Plainfield, N. J.; Baltimore Medical College, 1900; on the staff of the Muhlenberg Hospital, Plainfield; for many years secretary of the board of health of Plainfield and formerly registrar of vital statistics; aged 62; died, June 20, of chronic arthritis.

Hugh Edgar Ferguson, Toronto, Ont., Canada; University of Toronto Faculty of Medicine, 1914; medical officer of health of Forest Hill village; served during the World War; on the staffs of the Toronto East General Hospital and the Toronto Western Hospital; aged 59; died, June 21.

Louis Goldstein, Beaumont, Texas; College of Physicians and Surgeons of Chicago, 1886; member of the State Medical Association of Texas; past president of the Jefferson County Medical Society; on the staff of the Hotel Dieu Hospital; aged 77; died, June 25, of bronchopneumonia.

Thomas Hayes Kinnaird, Lexington, Ky.; University of the City of New York Medical Department, 1881; member of the Kentucky State Medical Association; aged 84; died, June 25, in St. Joseph's Hospital of chronic pyelonephritis with nephrolithiasis and bronchopneumonia.

Felix Cohn ⊕ New York; Universität Heidelberg Medizinische Fakultät, Baden, Germany, 1884; member of the American Academy of Ophthalmology and Oto-Laryngology; on the staffs of the Montefiore, Beth Israel and Lenox Hill hospitals; aged 78; died, June 2.

Hal H. Hazlett, Topeka, Kan.; Barnes Medical College, St. Louis, 1897; member of the Kansas Medical Society; veteran of the Spanish-American War; for many years on the staff of the Christ's Hospital; aged 65; died, June 4, of carbon monoxide poisoning.

E. W. Hoylman, Secondcreek, W. Va.; University of the South Medical Department, Sewanee, Tenn., 1906; member of the West Virginia State Medical Association; aged 64; died, June 22, in a hospital at Ronceverte of abscess of the gall-bladder and uremia.

M. Jean Wilson ⊕ Warsaw, N. Y.; University of Buffalo School of Medicine, 1885; formerly village president and member of the board of education of the high school; aged 78; on the staff of the Wyoming County Community Hospital, where he died, May 26.

Dixie Navarro Foster, Franklin, La.; Tulane University of Louisiana School of Medicine, New Orleans, 1889; for many years superintendent of education of the parish; aged 76; died, June 15, in the Iberia General Hospital, New Iberia, of cerebral hemorrhage.

Alonzo Woodford Little, Kansas City, Kan.; University Medical College of Kansas City, Mo., 1900; member of the Kansas Medical Society; served during the World War; aged 59; died, June 8, in the Veterans Administration Facility, Wadsworth.

George Edward Hearst ⊕ Cedar Falls, Iowa; State University of Iowa College of Medicine, Iowa City, 1904; on the staff of the Sartori Memorial Hospital; aged 60; died, June 9, in the Illinois Central Hospital, Chicago, of pulmonary embolism.

Frederick August Seemann, National City, Calif.; Hahne-mann Medical College and Hospital, Chicago, 1891; Rush Medical College, Chicago, 1897; aged 73; died, May 22, in the San Diego County Hospital, San Diego, of carcinoma of the esophagus.

Daniel Smith Harrop, West Warwick, R. I.; Georgetown University School of Medicine, Washington, D. C., 1915; chairman of the school committee; served during the World War; aged 48; died, June 8, in St. Joseph's Hospital, Providence.

James Kennedy Corss ⊕ Newport News, Va.; University of Pennsylvania Department of Medicine, Philadelphia, 1892; fellow of the American College of Surgeons; aged 70; on the staff of the Elizabeth Buxton Hospital, where he died, June 6.

Horace Nelson Mateer, Wooster, Ohio; University of Pennsylvania Department of Medicine, Philadelphia, 1883; for many years professor of biology at the University of Wooster; aged 83; died, June 10, of arteriosclerosis and myocarditis.

Benjamin William Kelly ⊕ Aitkin, Minn.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1897; past president of the Aitkin County Medical Society; served during the World War; aged 65; died, June 4.

George Everett Murphy, Olympia, Wash.; University of Oregon Medical School, Portland, 1912; member of the Washington State Medical Association; aged 62; died, May 18, in St. Peter's Hospital, of cerebral hemorrhage and pneumonia.

James Henry Divine, Palisade, Colo.; College of Physicians and Surgeons, Keokuk, Iowa, 1879; Bellevue Hospital Medical College, New York, 1883; aged 92; died, May 18, in the Fitzsimons Hospital, Denver, of arteriosclerosis.

Arthur W. Blunt, Clinton, Iowa; Chicago Homeopathic Medical College, 1878; member of the Iowa State Medical Society; aged 84; on the staff of the Jane Lamb Hospital, where he died, June 17, of cerebral hemorrhage.

Orpheus E. Current, Farmland, Ind.; Medical College of Indiana, Indianapolis, 1897; member of the Indiana State Medical Association; on the staff of the Ball Hospital, Muncie; aged 67; died, June 18, of coronary thrombosis.

Charles L. King, Whitesboro, Texas; University of Louisville (Ky.) Medical Department, 1883; member of the State Medical Association of Texas; for many years health officer; aged 80; died, June 14, of cerebral hemorrhage.

Tekla Amalia Josefina Berg, Lynn, Mass.; Tufts College Medical School, Boston, 1898; member of the Massachusetts Medical Society; aged 70; died, June 8, of cerebral hemorrhage, abdominal tumor and arteriosclerosis.

Alfred Alexander Macleay, Manchester, N. H.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1895; aged 69; for many years on the staff of the Notre-Dame de Lourdes Hospital, where he died, June 1.

William Sleeper Windle, Oskaloosa, Iowa; Kentucky School of Medicine, Louisville, 1897; formerly professor of physiology and biology at the William Penn College; aged 74; died, May 28, of coronary artery disease.

Fred S. Williams, Shelton, Conn.; Chicago Homeopathic Medical College, 1904; Northwestern University Medical School, Chicago, 1905; member of the Connecticut State Medical Society; aged 57; died, May 5.

David C. Nolan ⊕ Saratoga Springs, N. Y.; Albany (N. Y.) Medical College, 1906; senior member of the medical staff of the Saratoga Hospital and a member of the executive committee; aged 58; died, May 17.

John Lewis Harvey ⊕ Simpsons, Va.; University College of Medicine, Richmond, 1909; member of the county board of health; formerly member of the state legislature; aged 53; died, June 27, of angina pectoris.

Louis Mark Alofsin ⊕ New York; Long Island College Hospital, Brooklyn, 1907; served during the World War; on the staff of the French Hospital; aged 55; died, June 2, of carcinoma of the rectosigmoid.

Herbert Richard Holme, Toronto, Ont., Canada; University of Toronto Faculty of Medicine, 1909; served during the World War; on the staff of the Toronto East General Hospital; aged 53; died, June 5.

James Frederick Gaylord ⊕ Springfield, Mass.; Dartmouth Medical School, Hanover, N. H., 1914; served during the World War; aged 49; died, June 8, in the Springfield Hospital of cerebral hemorrhage.

David Howard Gibson, Cambridge, Mass.; Tufts College Medical School, Boston, 1921; member of the Massachusetts Medical Society; aged 53; died, June 8, in the United States Naval Hospital, Chelsea.

Roy Lee Laird ⊕ Detroit; University of Michigan Medical School, Ann Arbor, 1917; served during the World War; on the staff of the Harper Hospital; aged 45; died, June 17, of coronary thrombosis.

James Nathan Gee, Bethel, Texas; Vanderbilt University School of Medicine, Nashville, Tenn., 1890; for many years member of the county school board; aged 72; died, June 30, of coronary occlusion.

Charles Aulden Emes, Twin Falls, Idaho; University Medical College of Kansas City, Mo., 1897; on the staff of the Twin Falls County General Hospital; aged 65; died, June 3, of coronary occlusion.

Richard Pitman Lewis, Tujunga, Calif.; University Medical College of Kansas City, Mo., 1910; served during the World War; aged 52; was burned to death, June 30, when his home caught fire.

Francis James Grandfield ⊕ New Boston, Mich.; Detroit College of Medicine, 1909; bank president, justice of the peace and health officer; aged 58; was found dead, June 3, of coronary thrombosis.

Henry Holmes Hunter, Whaleyville, Va.; Medical College of Virginia, Richmond, 1900; member of the Medical Society of Virginia; member of the county school board; aged 64; died, June 17.

Patrick Joseph Mangan, San Francisco; Cooper Medical College, San Francisco, 1896; member of the California Medical Association; aged 73; died, May 31, of arteriosclerotic heart disease.

Oscar Jacobs MacLaughlin ⊕ Hot Springs National Park, Ark.; University of Arkansas School of Medicine, Little Rock, 1927; aged 41; died, June 2, of injuries received in an automobile accident.

Alexander William Chisholm, Margaree Harbour, N. S., Canada; College of Physicians and Surgeons, Baltimore, 1894; for many years a member of the House of Commons; aged 70; died, May 4.

Frank Joseph Parizek, Los Angeles; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1904; aged 56; died, May 7, of chronic myocarditis and arteriosclerosis.

George French Campbell, Los Angeles; Barnes Medical College, St. Louis, 1904; veteran of the Spanish-American War; formerly physician in the Indian Service; aged 70; died, June 17.

Charles Richard Hunt, New Bedford, Mass.; Boston University School of Medicine, 1887; formerly physician to the Bristol County Jail and House of Correction; aged 83; died, June 14.

J. Leonard Gratton, Montreal, Que., Canada; M.B., Laval University Medical Faculty, Montreal, 1906 and M.D., 1908; on the staff of the Verdun General Hospital; aged 55; died, May 19.

Louis Simeon Gendreau, St. Norbert, Man., Canada; Manitoba Medical College, Winnipeg, 1896; aged 65; died, June 12, of cerebral thrombosis, arteriosclerosis and diabetes mellitus.

Nathan A. Jones, Trilla, Ill.; College of Physicians and Surgeons, Keokuk, Iowa, 1896; member of the Illinois State Medical Society; aged 71; died, June 18, of cerebral hemorrhage.

John Frederick Stevens, Millinocket, Maine; Dartmouth Medical School, Hanover, N. H., 1899; aged 70; died, May 30, at Bangor of bronchopneumonia and hypertrophy of the prostate.

George W. Dwinnell, Montague, Calif.; Rush Medical College, Chicago, 1885; aged 78; died, May 5, in the Cedars of Lebanon Hospital, Los Angeles, of cardiorenal syndrome.

Peirson Sterling Page, Andover, Mass.; University and Bellevue Hospital Medical College, New York, 1899; member of the Massachusetts Medical Society; aged 67; died, May 23.

Charles Herbert Gumaer, San Diego, Calif.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1878; aged 85; died, May 7, of carcinoma of the prostate.

Fred P. Eastman, South Bend, Ind.; Detroit College of Medicine, 1892; member of the Indiana State Medical Association; aged 78; died, June 17, of cerebral hemorrhage.

C. O. Guimont, Quebec, Que., Canada; Laval University Faculty of Medicine, Quebec, 1895; at one time head of the city medical research laboratory; aged 64; died, May 10.

Henry Irwin Durgin ♂ South Eliot, Maine; University of the City of New York Medical Department, 1889; aged 75; died, June 15, of cerebral hemorrhage and hypertension.

James Edward Donnelly, Terre Haute, Ind.; Rush Medical College, Chicago, 1901; member of the Indiana State Medical Association; aged 67; died, June 7, of myocarditis.

John Hermanies ♂ Mariemont, Ohio; Drake University College of Medicine, Des Moines, 1913; aged 56; died, June 14, in the Deaconess Hospital, Cincinnati, of carcinoma.

Henry Jackson Deaver, Sabetha, Kan.; Starling Medical College, Columbus, 1892; member of the Kansas Medical Society; aged 73; died, June 19, of lymphosarcoma.

Curtis Oscar Mabey, New Providence, Iowa; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1888; aged 81; died, June 20, of cerebral thrombosis.

George Preston Allen, San Francisco; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1879; aged 84; died, May 30, of arteriosclerosis.

William M. B. Cox, Lincoln Acres, Calif.; Memphis (Tenn.) Hospital Medical College, 1904; aged 61; died, May 18, of coronary sclerosis and hepatic cirrhosis.

Marion C. Low, South Haven, Mich.; Hahnemann Medical College and Hospital, Chicago, 1895; aged 75; died, June 6, in Bangor of heart disease and bronchitis.

Walter Scott Hanley, North Wales, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1898; aged 65; died, May 16, of coronary thrombosis.

Louis George Corbett, Tampa, Fla.; Medical College of the State of South Carolina, Charleston, 1883; aged 83; died, June 17, of carcinoma of the stomach.

Robert Jonathan Crawford, Winnipeg, Man., Canada; University of Toronto Faculty of Medicine, 1891; aged 70; died, June 8, of coronary thrombosis.

Robert Dwight Wilson, Hermosa Beach, Calif.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1898; aged 64; died, May 5.

Frederick Joseph Haerer, Cape May, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1892; aged 77; died, June 22, of chronic nephritis.

George Robert Hagerman, Kipton, Ohio; Western Reserve University Medical Department, Cleveland, 1880; aged 82; died, June 6, of arteriosclerosis.

James Christian Figenshau, Billings, Mont.; Hahnemann Medical College and Hospital, Chicago, 1913; aged 65; died, June 13, of coronary disease.

Edward B. Moles, Brockville, Ont., Canada; McGill University Faculty of Medicine, Montreal, Que., 1896; died, May 28, of coronary thrombosis.

Carl Jesse Koontz, Burlington, Iowa; Marion-Sims College of Medicine, St. Louis, 1899; aged 63; died, June 14, of coronary thrombosis.

Morton Howland, Huntington, Ind.; Medical College of Ohio, Cincinnati, 1886; aged 76; died, June 17, of endocarditis and arteriosclerosis.

John Laughlin MacMillan, Westville, N. S., Canada; Dalhousie University Faculty of Medicine, Halifax, 1931; aged 38; died, May 28.

George Flanagan Shaw, Toronto, Ont., Canada; McGill University Faculty of Medicine, Montreal, Que., 1893; aged 76; died, May 13.

Lloyd Newcomb Beckwith, Trail, B. C., Canada; University of Manitoba Faculty of Medicine, Winnipeg, 1930; aged 44; died, May 11.

Thomas M. Culver, Anderson, Ind.; Indiana Eclectic Medical College, Indianapolis, 1886; aged 86; died, June 28, of chronic nephritis.

John K. Geary, Fort Wayne, Ind.; Fort Wayne College of Medicine, 1887; aged 87; died, June 29, in Columbia City of diabetes mellitus.

Orin Eastland, Shreveport, La.; Missouri Medical College, St. Louis, 1882; aged 81; died, June 10, in Palestine, Texas, of pyelonephritis.

Brainard B. Gracy, Smyrna, Tenn.; University of Louisville (Ky.) Medical Department, 1876; aged 89; died, May 3, of prostatitis.

Percy Bissell Grant, Winnipeg, Man., Canada; Manitoba Medical College, 1908; aged 59; died, June 3, of carcinoma of the bladder.

William W. Carmichael, Hampton, Ga.; Southern Medical College, Atlanta, 1886; aged 74; died, June 7, of arteriosclerosis.

William Francis Gavin, Regina, Sask., Canada; Queen's University Faculty of Medicine, Kingston, 1906; aged 58; died, May 24.

John James MacDonald, New Glasgow, N. S., Canada; Halifax Medical College, Halifax, N. S., 1910; aged 54; died, May 17.

William H. Kelly, Spartanburg, S. C.; University of Tennessee Medical Department, Nashville, 1885; aged 77; died, May 22.

Neil Malloch, Ottawa, Ont., Canada; McGill University Faculty of Medicine, Montreal, Que., 1897; aged 69; died, June 4.

Frank H. Escher, Biteley, Mich.; National Medical University, Chicago, 1902; aged 71; died, June 18, of cardiorenal disease.

Bittle Cornelius Keister, Washington, D. C.; College of Physicians and Surgeons, Baltimore, 1882; aged 82; died, May 3.

George C. Ferrier, South Mountain, Ont., Canada; Queen's University Faculty of Medicine, Kingston, 1900; died, May 5.

Louis P. Linss ♂ Cincinnati; Medical College of Ohio, Cincinnati, 1903; aged 70; died, June 25, of coronary occlusion.

Walter M. Shepherd, Wiggins, Miss. (licensed in Mississippi in 1906); aged 74; died, May 21, of valvular heart disease.

Charles David Gibson Mack, Weymouth, Mass.; Boston University School of Medicine, 1895; aged 66; died, May 1.

John Robert Serson, Mimico, Ont., Canada; University of Toronto Faculty of Medicine, 1905; aged 61; died, May 29.

Alfred Winthrop Myrick ♂ Randolph, Mass.; Tufts College Medical School, Boston, 1909; aged 54; died, May 10.

Arthur L. Mitchell, East Aurora, N. Y.; Homeopathic Hospital College, Cleveland, 1883; aged 78; died, May 13.

Melvin Byron Huff, Long Beach, Calif.; University of Buffalo School of Medicine, 1885; aged 82; died, June 7.

H. H. Kemp, Senoia, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1894; aged 83; died, June 17.

Joseph Wilson Blair, Latrobe, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1888; aged 79; died, May 3.

Isidor Shulman, Brooklyn; Long Island College Hospital, Brooklyn, 1912; aged 53; died, May 9, of heart disease.

Lamar Preston Fordham, Pavo, Ga.; Atlanta College of Physicians and Surgeons, 1902; aged 59; died, June 9.

Jay Alexander Lipnick, Brooklyn; Medical College of Virginia, Richmond, 1916; aged 47; died, June 9.

Lemuel B. McWhorter, Chattanooga, Tenn.; Atlanta (Ga.) Medical College, 1889; aged 77; died, May 23.

C. T. Hackleman, Pleasant View, Mo. (licensed in Missouri in 1884); aged 88; died, May 17.

W. S. Davis, Owensville, Ark. (licensed in Arkansas in 1903); aged 83; died, June 13.

Bureau of Investigation

GERMEX

A "Cancer Cure" Fraud

The high-sounding Duncombe Research Laboratory (also called Laboratories) of Detroit and Rochester, Mich., first came to the attention of the Bureau of Investigation of the American Medical Association in November 1933, through an inquiry from an Illinois physician who said a patient had been taking the concern's "cancer cure." A few months later the Bureau received a piece of the advertising, a card which mentioned the following products:

"Germex, External and Internal (Carcinoma)"
 "Germex, Intra-Venous (Carcinoma)"
 "Hindoo Prescription (Genital)"
 "Epi-Phi (Athletic Foot)"
 "Non-Poisonous Antiseptics"

The advertising obviously was directed to the layman, as it read in part:

"Germex—a Non-Poisonous Antiseptic—Destroying Parasites and Bacteria—This card may mean good health to you again, or to someone you are interested in. We welcome your case, whether it is cancer, ulcers of the stomach, pernicious anemia, syphilis, arthritis, or any other disease which has been caused by parasite or bacteria.

"Germex is not a patent medicine, but rather a pharmaceutical—a new discovery to be used by physicians and public as well.

"In cancer cases the pain is relieved in 24 hours and the odor will disappear in 48 hours, according to the condition of the patient.

"Where others have failed heretofore, GERMEX will do the trick."
 ("Trick" appears to be the right word.—Ed.)

In March 1934 a person signing himself M. F. Booth but not making clear his connection with the enterprise sent a letter

PHONE TOWNSEND 8-5798

DUNCOMBE RESEARCH LABORATORY

14049 WOODWARD AVENUE

DETROIT

PRODUCTS

HINDOO PRESCRIPTION (GENITAL) NON-POISONOUS ANTISEPTICS
 EPI-PHI (ATHLETIC FOOT) GERMEX, EXTERNAL AND INTERNAL (CARCINOMA)
 GERMEX, INTRA-VENOUS (CARCINOMA)

GERMEX

A Non-Poisonous Antiseptic

DESTROYING PARASITES AND BACTERIA

THIS CARD MAY MEAN GOOD HEALTH TO YOU again, or to someone you are interested in. We welcome your case, whether it is CANCER, ulcers of the stomach, pernicious anemia, syphilis, arthritis, or any other disease which has been caused by parasite or bacteria.

OVER

One side of Germex advertising card (reduced).

written by hand on the stationery of a Detroit hotel to the executive secretary of the Ohio State Medical Society. With it he sent a card of the kind described above. According to this letter Germex is "not a new remedy but has been tested thoroughly for years, and is now to be given physicians as a cure for such complaints as the card indicates, as well as tonsillitis, diabetes and many other cases. . . ."

Mr. Booth's letter proceeded to let the medical society in on the ground floor of a supposedly alluring proposition:

"Laboratories are being opened in different cities. If you would like the exclusive [rights] for the state of Ohio for \$1,250 they will send you \$250.00 worth of Germex. . . . Hoping this opportunity will be of sufficient interest to you that you will investigate it without delay as it is so remarkable in its effects."

The Ohio society naturally did not care to avail itself of this golden opportunity, and so passed the "offer" along to the Bureau of Investigation files, where it still reposes with others of its kind. To a medical official in California, however, Booth is said to have offered the exclusive Germex agency in that

state for as much as \$6,000, the idea apparently being that the pickings of quackery are better in that sun-kissed land, and hence worth the greater price.

Around the same time the exploiter, signing himself "Dr. T. H. Duncombe, D. C." wrote to Food and Drug officials of Michigan:

"We are about to incorporate and to manufacture a new secret formula, which we have been selling to the doctors throughout the city. . . . It is our desire to receive information concerning the sale to the public. It is a synthetic, non-poisonous antiseptic, that is used externally, internally and intra-venously.

"We are desirous to retain the active principal a secret, until such time it is recognized for its merit. We can supply letters with affidavits from medical men and others, who are using it with success for pathogenic bacteria destruction, which have never here-to-fore yielded to treatment including Pernicious Anemia, arthritis, syphilis and cancer. We are also testing it out for tubercle bacillus. It is also a success for septicemia [sic] and many other skin diseases, fistula and etc.

"We will, I presume, be required to register several preparations as they are produced for special purposes.

"Germex is a name for the active ingredient, synthetically produced, and is a name only, as for instance: Aspirin had to be given a name, however, there are several chemical formulas for aspirin, as to its molecular arrangement; it has been tested out thoroughly as to its toxic content, is harmless used in any manner, in fact, a physician drank a four ounce bottle here in the laboratory, while the dose is one dram.

"The founder is an old druggist since 1889, and is competent to pass upon the product."

Soon afterward, Duncombe made overtures to the Council on Pharmacy and Chemistry of the American Medical Association for recognition of Germex. He named physicians who, he intimated, had achieved remarkable results with it. Apparently they had not taken the trouble to learn its composition, for Duncombe wrote:

"The physician usually in these cases makes the statement that they cannot believe their eyes and see what Germex does and are not interested in what it is. [Italics ours.—Ed.] We . . . are endeavoring to keep the formula a secret, otherwise pharmaceutical manufacturers will step in and confiscate it from us. And as we have been doing laboratory for over thirty years, it would hardly be fair to have it taken from us. . . ."

"Duncombe Research Laboratory is today owned only by my son and my self. However we are hoping to come out through the medical association rather than other sources, and allow medical men to invest in a company that may be nationally advertised for the sake of humanity. We admit it sounds contrary to the present day teachings, but Germex really does what we claim with consistency. . . ."

Duncombe was told of course that, if he would not reveal the formula, Germex could receive no consideration from the Council. Following further correspondence he finally sent the Council a partial description of Germex, as follows:

"Germex is a Carbo-hydrate in solution, containing 10% by volume of alcohol. The molecular definition or anatomical construction has not definitely been proven. . . . A solution of coal tar, with undesirable constituents removed . . . a brown Liquor, containing 10% by volume of alcohol. . . . No odor, a peculiar bitter herbaceous taste, non-poisonous,—no alkaloidal contents . . . contains Strepto-Bacillus, a saprophyte that is harmless . . . Antiseptic, an agent that prevents the development of bacteria . . . has the power of driving out pathogenic bacteria, without destroying the young cells and islets, or causing an abnormal growth of the tissue. It will kill parasites."

In replying to Duncombe the Council pointed out that he had presented no acceptable evidence that Germex was a scientific product. His answer implied that the thing should be accepted on its face. In April 1935, however, he finally informed the American Medical Association that he was willing to divulge the formula of Germex and asked how to proceed. He was sent a book of the rules for submitting a product to the Council on Pharmacy and Chemistry. He never replied.

Into the picture came next the Federal Trade Commission, which, on May 24, 1937, issued a Cease and Desist Order against Tyrrell H. Duncombe, trading as the Duncombe Research Laboratory, prohibiting him from representing that Germex is of any benefit in cancer, pneumonia, tuberculosis, ulcer, pernicious anemia, arthritis, septicemia, diabetes or any other ailment, or is antiseptic in its action, or will destroy or prevent the growth of disease-bearing germs.

Then came the investigation by the Post Office Department. The memorandum on the case from Hon. Calvin O. Hassell, Acting Solicitor for the Department, set forth the following facts:

Duncombe claimed to have attended Ontario College of Pharmacy at Toronto in 1889 and thereafter to have run a drug store at St. Thomas, Ont., in which connection he "discovered" and began selling Germex. Later he conducted a drug store in Detroit for several years, until he left it to sell Germex to the public through the mails.

The memorandum went on to show that although Duncombe claimed that as the result of the Federal Trade Commission's action against him he had discontinued the claims the Post Office was now declaring fraudulent, nevertheless the latter agency was able to find evidence that he was still sending out literature that was typically offensive and misleading, representing the product as a germicide and a remedy for "many heretofore considered incurable diseases namely: cancer, sugar-diabetes, pernicious anemia, appendicitis . . . and other bacteria and parasitic diseases, including eczema." It was found he was also using a printed card reading in part:

"Germex

A peculiar bitter, which acts by bitterizing the fluids and secretives of the body, on which bacteria live, without any noticeable or important therapeutical action. . . ."

This bitter was found by a government chemist to be chiretta, an herb resembling gentian in action.

Further, a test made by a government bacteriologist showed Germex to be "absolutely devoid of any inhibitory or antiseptic properties whatsoever." In fact, it was actually found to contain "certain bacilli, a form of parasite and germ life. Hence the evidence clearly showed that the promoter's claim that Germex was both an internal and an external antiseptic was false and fraudulent, and Duncombe offered no evidence to the contrary. A fraud order was accordingly issued on Sept. 20, 1938, against the Duncombe Research Laboratory, Duncombe Research Laboratories and their officers and agents as such.

The Post Office memorandum also pointed out that, though Duncombe might qualify as a chemist or pharmacist, he had had no medical training. In one of his letters to the American Medical Association he claimed:

"While my family are a consecutive line of M.D.s, I am naturally interested in seeing that this product should be with them, however so far others, especially the Osteopaths are taking it up vigorously, I have dodged from being a regular practitioner, having seen the strenuous life as a boy, and took a course as a chemist, then did take a course when I was forty years of age as a chiropractor, but have been retired, and have been devoting my life in the laboratory. Having spent 35 years as a druggist, but always had a laboratory."

Also in this correspondence Duncombe gave the name of a Florida physician who, he claimed, endorsed Germex. When the physician was asked whether this was true, he replied that Duncombe had brought him some patients and furnished the medicine for test treatments but paid him nothing for his services; that one case cited by Duncombe apparently responded to treatment with Germex, but three cases following it failed to show any improvement whatever. He added the comment:

"I found the remedy to be perfectly harmless and without reaction. This is the extent of my observation with Germex, and this being so limited, I am not in a position to pass on the efficacy of the remedy, but it is my opinion that the remedy is inert."

The physician added that when he discovered that his name was being used by Duncombe in the promotion of Germex he immediately demanded that it be deleted from the literature. He reported also that Duncombe wrote him in May 1932 promising not to use his name further, but in July 1935 the physician was informed that Duncombe was still using his name.

There may be lower standards of ethics than those which involve deceiving cancer victims with a promise, direct or implied, to cure them with nostrums, but if so they must be rare.

Correspondence

POTASSIUM CHLORIDE IN ALLERGY

To the Editor:—An article by Benson Bloom appearing in THE JOURNAL (The Use of Potassium Salts in Hay Fever, Dec. 17, 1938, p. 2281) extolled the virtues of potassium salts in hay fever. Soon the lay press joined in announcing a new "cure" for hay fever and other allergic states.

My practice is limited to allergy, and I received numerous inquiries from physicians and patients pertaining to the effectiveness of potassium chloride in hay fever and other allergies. As a result, I have undertaken a personal study of sixty-four cases to date, in my private practice, covering the cases of tree and grass pollinosis, a few angioneurotic edemas and asthma.

The patients were given ten 5 grain (0.3 Gm.) tablets of potassium chloride to be taken, when necessary, three times a day after meals with at least one glassful of water.

The results reported by Dr. Bloom differ strikingly from my own observations. More than half not only were not relieved but in addition had severe epigastric pain and/or dizziness, tachycardia and other untoward disturbances. With one or two exceptions, those who were relieved slightly were given acetylsalicylic acid (except, of course, those sensitive to this drug) and, in most instances the acetylsalicylic acid produced greater relief than the potassium chloride.

My experiences at this time cause me to believe that potassium chloride is of limited or questionable value in hay fever and other allergies and that words of caution should be published.

DAVID LOUIS ENGELSHER, M.D., New York.

"THE MARYLAND MEDICAL EXAMINER ACT"

To the Editor:—In the July 22 issue of THE JOURNAL appeared an editorial entitled "The Maryland Medical Examiner Act." From what I can learn of the Maryland act, I am of the opinion that it is a good act. The Michigan coroner law has many faults as it now stands. Principally, it permits a person without any qualifications to occupy the position of coroner. Hence there are barbers, real estate men, undertakers and men of what not occupations represented. However, in my opinion it was unwise to pass an act making the office, known by whatever name, the expensive, centralized political machine provided by this act.

There was no provision made for changing the occupant of the head office for any reason whatever. He could hire and fire all the subofficers throughout the state at his pleasure, giving him despotic privileges. According to the law, qualifications for the office did not of necessity mean a medical education.

I advocated a change in the law providing medical qualifications with perhaps some additional training at conventions or elsewhere including drugstore poisons, such as fumigators, insecticides, pest exterminators (rats, mice and the like); general police work in ballistics, finger printing, moulage and methods of preservation of evidence, leaving the setup as it is at present.

Because of these inconsistencies in the law I was one of several persons who objected to its passage. There were several petty matters that also aided in bringing about its defeat.

I hope you will not feel that I am writing this in criticism but I am quite sure you did not understand the Michigan act as it was presented.

HORACE R. COBB, M.D.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

ARSPHENAMINIZED BLOOD FOR TRANSFUSION

To the Editor:—In an article by Clara C. Kast, C. W. Peterson and J. A. Kolmer, in the *American Journal of Syphilis, Gonorrhea and Venereal Diseases* (23:150 [March 23] 1939), the authors suggest the practicability of using syphilitic or doubtful donors for transfusions by first treating the citrated blood with neoarsphenamine or arsphenamine. Is this an acceptable procedure? Given a situation in which an emergency exists and in which equipment is available for cross matching but not for performing a serologic test, is one justified, medically and legally, in using the procedure as given in this article?

Karl W. Linsenmann, M.D., Pontiac, Mich.

ANSWER.—The procedure described by Kast, Peterson and Kolmer, which is supported by the independently conducted studies of Eagle on the spirillicidal effectiveness of solutions of the arsphenamines in vitro, offers a useful recourse in uncontrollable emergencies. It should not, in the present state of knowledge, be employed as routine practice. Even more should it be emphasized that the proper blood for blood transfusion is the blood of a healthy person, free from syphilis or other transmissible or allergic disease. The substitution of the treated blood of an unhealthy person under other than circumstances of extreme and uncontrollable emergency might well be regarded as medically and medicolegally questionable.

It cannot be denied that there have always existed and probably always will exist loopholes in the controllability of the syphilis factor in donors' blood under almost any conditions of practice. This is due to the fact that an individual may be the carrier of *Spirochaeta pallida* from a recent infection before the appearance of any clinical evidence of the disease whatever and before any serologic test now known becomes reliably positive. The question might then well be raised whether it is not obligatory for the absolute protection of the patient to treat all blood for transfusion in accordance with one of the procedures suggested by Kast, Peterson and Kolmer. Were such a practice to gain general acceptance, it would indeed constitute medicolegal protection and defense to be able to show that the blood of a person alleging the transmission of syphilis in blood transfusion had been rendered innocuous for the transmission of the disease by such a procedure. The use of blood banks with the questions involved in the viability of *Spirochaeta pallida* under refrigeration conditions and the possible desirability of introducing antispirechetical control into the use of such blood offers a still further interesting field for speculation and investigation.

Taking it all in all, one may say that at the present time it would be inadvisable to allow the discovery of any spirocheticidal device to lower the highest possible standards for the examination of prospective donors with reference to syphilis and the protection of the donee against the slightest element of avoidable risk or doubt from this direction. In patients in a critical condition, it is quite conceivable that the added arsphenamine might be the cause of a critical reaction of some sort. In cases of unrecognized but previously established sensitivity to the drug, exfoliative dermatitis might follow, for it has been shown that as little of the arsenical as would adhere to the wall of a syringe rinsed in cold water is sufficient to cause an explosion of exfoliative dermatitis in an ultrasensitive patient. It is obvious therefore that, despite the usual lack of reaction to arsphenaminized transfusion blood described by Kast, Peterson and Kolmer, such complete absence of reaction is not likely to be an invariable experience. The treatment of transfusion blood with an arsphenamine solution therefore should in all probability remain an emergency measure designed to afford as much protection as possible in cases in which investigation of the donor has been perforce inadequate. In the modern hospital, equipment for the quick performance of Kahn or Kline elimination procedures need not be lacking. On the other hand, in such conditions as prevail in the field on engineering projects like the Panama Canal Zone during the period of construction, emergency might even make undardonable the failure to use the blood of known syphilitic patients in the attempt to save life. It might well be claimed, however, after the work of these authors becomes reasonably well

known, that a neoarsphenamine ampule, with instructions for adding water and diluting, should form part of emergency transfusion kits for use where hospital equipment for tests cannot be made available. The legal aspects have not, so far as is known, been tested by the courts.

SCOPOLAMINE AND CACTOID

To the Editor:—A man aged 42 has been taking 1/200 grain (0.3 mg.) of scopolamine hydrobromide with 1/120 grain (0.5 mg.) of cactoid each night for two or three months for nervousness and insomnia. He has asked me what, if any, ill results may follow their use and I am thus passing the query on to you.

N. R. Harlan, M.D., Freeport, Ill.

ANSWER.—It is regrettable that cactoid (at one time called cactin) is still being foisted on the public. It is one of the preparations made from *Cactus grandiflorus* about which there has been a great deal of controversy. Since 1908 the Council on Pharmacy and Chemistry has constantly pointed out the worthlessness of these preparations. In 1907 R. A. Hatcher stated that he could find no evidence of pharmacologic action. S. A. Matthews in 1908 showed that cactin had no effect when a thousand times the recommended dose was administered. In 1910 the Council on Pharmacy and Chemistry reviewed the evidence for the value of *Cactus grandiflorus* and concluded that no available preparation was a reliable remedy. Thus it appears that cactoid has no therapeutic value and no toxic or cumulative action and consequently there would be little if any effect if it should be taken in the dosage mentioned over a long period of time. Scopolamine (hyoscine) is mainly sedative in all doses, although there is a great difference in individual response owing to idiosyncrasy, which also causes variation in toxicity. Doses of from 1 to 3 mg. ($\frac{1}{60}$ to $\frac{1}{20}$ grain) of scopolamine hydrobromide generally produce fatigue, drowsiness and natural sleep in fifteen minutes. Scopolamine has advantages over morphine in that it quiets the reflexes and is not habit forming but produces unpleasant side effects of mydriasis, cycloplegia and excessive dryness. A certain degree of constipation may result, owing to lessened intestinal peristalsis if it is given regularly over a long period of time. In some cases after a long period of administration of atropine or scopolamine a lessened activity of the salivary glands has been noted after the withdrawal of the drug. The oculomotor effect is from five to ten times as pronounced as from an equal amount of atropine. The effect of scopolamine on the intra-ocular pressure is less than that of atropine. However, in glaucoma or in cases in which there is a tendency to an increased intra-ocular tension, or in patients past 50 years of age, its effect on the intra-ocular pressure when given continuously over a long period of time must be taken into consideration.

REFRACTORY RINGWORM

To the Editor:—I have a particularly refractory case of epidermophytosis of the hand. A woman aged 40, otherwise in good health, has repeatedly had eruption of the palm of the hand for several years. On examination she showed a scaly eruption spreading by the appearance of small vesicles on the periphery. Scrapings of these scales showed mycelial threads on microscopic examination. She has had many forms of treatment without good effect. In fact, the eruption was complicated by fissures, ulceration and secondary infection. Could you recommend any procedure that might be helpful? Is x-ray therapy of any value in this condition?

M.D., New York.

ANSWER.—This is a common problem of the dermatologist. As shown by Cleveland White and others, ringworm infections are great sensitizers, making it difficult to treat them with strong fungicides, and there are often general conditions that lower resistance, making the problem a complicated one. As in all inflammations of the skin, the treatment must be changed now and then to fit changed conditions in the skin. When fissures and pus infection are present, provided the patient's skin is not sensitized to mercury, one of the best applications is ammoniated mercury ointment. After the fissures have healed and the pus infection has disappeared, a crude coal tar ointment, such as one made of crude coal tar 2 Gm., zinc oxide 2 Gm. and enough petrolatum to make 30 Gm. may be applied thinly each evening. The old ointment should be removed with oil before each new application. This benefits the allergic reaction, if it is not too acute, and seems to control the ringworm infection. If it is impossible to keep the black ointment on during the day, ammoniated mercury ointment may be used by day, as much as circumstances permit, and the coal tar ointment applied at night. Of course the hands must be bandaged or gloved to protect the clothing from the black ointment, but care must be taken that such protective coverings are not thick, so as to keep the skin too warm.

QUERIES AND MINOR NOTES

963

Roentgen rays are decidedly beneficial in most cases of this kind. A quarter of a skin unit, 75 roentgens, may be given once a week. Low voltage rays, unfiltered, are preferred by most dermatologists. Benefit is seen usually after a few treatments. If, however, the case can be controlled by chemotherapeutic or other methods besides roentgen therapy, it is preferable to do so and save the roentgen rays, the total safe dose of which is strictly limited for future possible emergencies.

demonstrates that sodium ricinoleate can have no systemic reaction, since it is not absorbed, but must act locally within the alimentary tract. Some claim that it detoxifies the toxic substances present and prevents their absorption in an unaltered state. Sodium ricinoleate has never been accepted by the Council on Pharmacy and Chemistry.

Dorst and Morris (Bacterial Hypersensitivity of the Intestinal Tract: Its Treatment with Autogenous Vaccine and Sodium Ricinoleate, *Am. J. M. Sc.* 180:650-656 [Nov.] 1930; *ibid.* 178:631-632 [Nov.] 1929; The Use of Sodium Ricinoleate in Bacterial Hypersensitivity of the Intestinal Tract: Clinical Results, *Ann. Int. Med.* 4:396-397 [Oct.] 1930) claim that the underlying factor in the common of gastrointestinal cases was hypersensitivity to these organisms cause local spasms of the colon with ensuing constipation and other symptoms. They found positive cutaneous reactions to these bacteria, and when they gave sodium ricinoleate they reported that the cutaneous reactions faded and the patients improved. The drug has been used in thousands of cases and some good reports are given but, as stated, no clearcut results have been reported in cases in which food allergy has been definitely proved clinically and by cutaneous tests. In some cases of urticaria, symptoms have been ameliorated.

A search of the literature has revealed no reports of the use of kaolin in the field of food allergy. Theoretically, it might be useful by slowing down absorption of unaltered proteins.

INTRADUCTAL PRESSURE IN BILIARY OBSTRUCTION—BLOOD AMYLASE

To the Editor:—1. In obstruction in the common bile duct, what happens to the pressure in the bile system and how much pressure is necessary at the duodenal papilla to prevent the bile from flowing into the duodenum? How much pressure is necessary in the common bile duct to produce a visible obstructive jaundice? 2. Is an increase in the blood amylase a factor in the production of acute pancreatitis? Would the injection of amylase into the blood stream have any good or bad effect?

M.D., Iowa.

ANSWER.—1. The maximum pressures attained during obstruction of the common bile duct range from 300 to 375 mm. of bile. At this point the liver probably ceases to excrete bile and there may be a gradual decline in pressure (Herring, P. T., and Simpson, S.: *Proc. Roy. Soc. Med.* 79:517, 1907). The pressures attained after obstruction of the pancreatic duct have not been measured except indirectly; it is known (Bennett, A. L., and Still, E. U.: *Am. J. Physiol.* 106:454 [Nov.] 1933) that a secretory pressure of 18 mm. of mercury (250 mm. of water) may be developed within Wirsung's duct when the duct is closed. Presumably there is also a suppression of the flow of pancreatic juice due to obstruction. A good many determinations of intraductal pressure and of perfusion pressure (the pressure necessary to force fluid into the duodenum) within the common duct have been made in patients operated on for various types of biliary obstruction. The rise in ductal pressure produced by sphincteric spasm during a spontaneous colic is about 150 to 200 mm. of water. Following a more prolonged and complete obstruction of the sphincter, such as that produced by morphine, the intraductal and perfusion pressures increase to from 300 to 400 mm. of water. Perfusion pressures necessary to overcome the resistance of the sphincter after morphine have been recorded as high as 600 mm. of water.

These figures indicate that a continued and prolonged back pressure in excess of perhaps 300 to 400 mm. of bile is necessary to produce visible obstructive jaundice. Some of the voluminous, and rather contradictory, literature on this subject is cited:

Kipp, H. A.: Observations on the Variations in Bile Pressure in the Human Biliary Tract, *THE JOURNAL*, June 27, 1936, p. 2223.
McGowan, J. M.; Butsch, W. L., and Walters, W. L.: Pressure in the Common Bile Duct of Man, *ibid.*, June 27, 1936, p. 2227.
Potter, S. C., and Mann, F. C.: *Am. J. M. Sc.* 174:202 (Feb.) 1926.
Walters, W. L.; McGowan, J. M.; Butsch, W. L., and Knepper, P. A.: The Pathologic Physiology of the Common Bile Duct, *THE JOURNAL*, Nov. 13, 1937, p. 1591.

2. There is no reason to believe that temporary elevation of blood amylase has any particular effect on the organism. Definite increases have been noted in patients with common duct stone without apparent systemic effects. It is probable that some inactivating mechanisms come into play when high levels of serum amylase occur. Probably there would be no particular good or harm done by injecting serum amylase into the blood stream.

SODIUM RICINOLEATE AND KAOLIN IN FOOD ALLERGY

To the Editor:—Can you give me any information on sodium ricinoleate and kaolin taken internally for allergy due to foods?

Robert D. Kane, M.D., Elmhurst, N. Y.

ANSWER.—There are several papers that deal with the effect of sodium ricinoleate in gastrointestinal disturbances including those associated with hypersensitivity. Unfortunately, many of them do not clearly separate the allergic from such nonallergic conditions as ulcerative colitis, functional diarrhea and "auto-intoxication." Meyers, MacQuiddy and Baker (Sodium Ricinoleate: I. An Attempt to Determine Its Action in the Alimentary Tract, *J. Lab. & Clin. Med.* 19:462-473 [Feb.] 1934) found sodium ricinoleate colored with sudan IV and showed that it was not absorbed by the gastrointestinal tract, whereas butter and lard mixed similarly were easily absorbed, as shown by osits in the dorsal, omental and kidney regions. This

POSSIBLE PSEUDOHERMAPHRODITISM

To the Editor:—A woman aged 30 is feminine in body contour and structure but since childhood her thoughts, actions and mannerisms have been masculine. She escorts girls to dances, treats other girls as would any boy and is received socially as a boy not only by the girls but by the boys themselves. She is considerably above the average mentally, is quite well educated and is well liked by all. She is an embalmer and has a widespread reputation for excellent work. Her voice is rather masculine, as is her gait and general conduct. There is no beard nor is there a masculine distribution of hair on the lower part of the abdomen. She states that the mere closeness of other girls is gratifying to her but that there are no abnormal sexual practices. This could readily be doubted, since the girls with whom she associates are greatly attracted to her. She wears a light brassiere to compress her breasts and at three different times a small benign tumor has been removed from one breast. She is larger than usual. She has come to me asking that I amputate the breasts, giving as reasons for the request that she is in her way, that she is satisfied that she will never change in disposition and will not entertain a thought of marriage, that she is fearful because of the recurrent tumors that the breasts will become cancerous, and that they are an obstacle to pleasures she might otherwise have such as swimming. I am puzzled. 1. Is such an operation legal? 2. Is it in this case a mutilating operation? 3. Would the removal of both breasts be likely to affect her present good health in any manner? 4. Would their removal precipitate a changed mental state? (There are three cases of insanity on her mother's side among distant relatives.) 5. What are the probabilities of her having such a condition as a mixed ovary containing both ovarian and testicular tissue? 6. Are there any recent developments which by some test might reveal the presence of either a mixed ovary containing both ovarian and testicular tissue or testicular tissue elsewhere in the abdomen? I might add that the menses are normal and have been since she was 14. She insists that I do the operation at once and that she will go elsewhere if I refuse.

M.D., Idaho.

ANSWER.—1 and 2. Some of the abnormalities described here may be on a psychic basis and should receive the careful study of a trained psychiatrist. There seem to be no statutes or court decisions that would enable a categorical answer to these questions. Within limits, consent to cosmetic operations, if given by the interested persons with complete understanding of the purpose and possible results, is regarded as affording legal protection to the surgeon. Whether those limits extend so far as to validate consent given to cosmetic operations that must be looked on as involving material risk of life, or operations for the purpose of enabling a woman to masquerade more easily as a man, it is impossible to say.

3. No.
4. No.

5. It is assumed that the patient's internal and external genitalia have been examined and found normal. It is highly improbable that her ovaries would contain any testicular elements in the sense of an ovotestis or of an arrhenoblastoma, as in these instances physical characteristics are disturbed as well as and usually much more than mental characteristics.

6. No. The normal female excretes nearly as much androgenic material in her urine as does the normal male and as yet no correlation between the amounts of excreted androgens and the masculinity or femininity of behavior in women has been

established. Indisputably high androgen excretion has been found thus far only in malignant adrenal cortical neoplasms, for which there is no clinical evidence in the case cited. The role of the endocrines in the production of transvestitism and homosexuality is poorly understood.

COMPOSITION OF TABLE SYRUPS

To the Editor:—I was taught to prescribe dark karo syrup for children. I learn that the more recent graduates in medicine recommend light karo syrup for children. Which is correct?

E. S. Du Puy, M.D., Beckley, W. Va.

ANSWER.—Table syrups composed chiefly of corn syrup (glucose) are available in two general varieties: white syrups, which consist of a mixture of corn syrup and sugar syrup or rock candy syrup with added flavoring, and dark or "golden" syrups, which consist predominantly of corn syrup flavored with refiners' syrup. Sugar syrup and flavoring also may be added to the dark syrups. Flavoring may be vanilla extract, imitation maple flavor or vanillin and coumarin.

According to federal definition, glucose is a thick syrupy colorless product made by incompletely hydrolyzing starch or a starch containing substance and decolorizing and evaporating the product. It contains (on the basis of a specified density) not more than 1 per cent ash, which consists chiefly of chlorides and sulfates. Sugar syrup is the product made by dissolving cane or beet sugar in water. It contains not more than 35 per cent of water. Refiners' syrup is the residual liquid product obtained in the process of refining raw cane sugar. It contains not more than 25 per cent water and 8 per cent ash. Rock candy syrup is described as the syrup remaining after crystallization and removal of rock candy.

The range of composition of brands of white and dark table syrups accepted by the Council on Foods is as follows:

	Dark Syrup	Light Syrup
Moisture.....	23.0-26.4%	23.6-25.6%
Total solids.....	77.0-73.6%	76.4-74.4%
Ash.....	0.4-1.4%	0.2-0.4%
Fat (ether extract).....	0.0	0.0
Protein (N x 6.25).....	0.0-0.2%	0.0-0.2%
Reducing sugars (as dextrose).....	30.4-38.7%	27.7-36.5%
Total carbohydrates*.....	73.1-80.5%	74.1-76.1%
Calories per gram.....	2.9-3.2	2.9-3.1
Calories per ounce.....	82-91	82-88

* Chiefly dextrins, by difference.

It will be observed that the principal difference lies in the ash content of the two types of syrup. Each contains a high proportion of dextrins.

TREATMENT OF PAGET'S DISEASE

To the Editor:—What information can you give me on the present day treatment of Paget's disease of the bone? The patient has a blood calcium of 11 mg. The bones involved are the tibia, skull, clavicle and possibly the ulna.

C. F. Thomas, M.D., Port Huron, Mich.

ANSWER.—The treatment of Paget's disease is symptomatic. Since spontaneous remission of pain and arrest of the process are not uncommon, this possibility should be given consideration in all cases.

Kay and others have reported relief of pain in this disease by the administration of dried adrenal extract in doses of 5 grains (0.3 Gm.) taken three times a day. In some instances a lowering of the serum phosphatase has been observed in association with a relief from symptoms following administration of adrenal extract. The calcium and phosphorus content of the blood is usually within a normal range. Phosphatase is frequently high.

Relief of pain in Paget's disease by roentgen irradiation in moderate doses carried out under proper precautions is an adjunct in the treatment of this disease. The best results by roentgen therapy are obtained when the pain is localized in non-weight bearing bones.

In cases presenting marked decalcification of the bones, a diet high in calcium content supplemented by calcium in some form and vitamin D is indicated. (Calcium gluconate and vitamin D 15 grain [1 Gm.] tablets three times a day is a satisfactory means of administering calcium.)

Biopsy of the affected area of the bone has been done and cultures have been made; in a few instances positive cultures were obtained of a diphtheroid type of bacillus, and vaccines have been prepared. However, the results of this form of treatment have been irregular and on the whole have not been satisfactory.

NEOPRONTOSIL

To the Editor:—How long is it safe to give neoprontosil in 10 grain (0.65 Gm.) doses three times a day?

F. M. Sandifer, M.D., Greenwood, Miss.

ANSWER.—It is difficult to make a categorical statement regarding the length of time that it is safe to give neoprontosil or any of the sulfanilamide-containing chemotherapeutic agents.

Some patients have received from 30 to 60 grains (2 to 4 Gm.) of neoprontosil over a period of at least thirty days without any toxic manifestations. Some have received sulfanilamide daily for a period of more than a year without having ill effects from the long continued medication.

However, patients have been observed in whom the administration of 5 grains (0.3 Gm.) of neoprontosil produced a sharp febrile reaction. In any given individual one cannot say whether the administration of sulfanilamide or its derivatives will result in a toxic reaction or how long it is safe to give the drug.

Because of the inability to predict toxic manifestations, one must follow the individual patients carefully and constantly and be on the lookout for danger signs. As long as none appear it is safe to continue the drug. This product has not yet been accepted by the Council on Pharmacy and Chemistry.

NUMBNESS OF FINGERS AND TOES FROM OIL

To the Editor:—A man employed in one of the local steel mills has had a recent infection with syphilis and is responding well to therapy with arsenicals and bismuth. This man reported to me several weeks ago that he had noticed numbness of the tips of his fingers and toes, unassociated, however, with any loss of motor power or paresthesias. On inquiring into the details of his duties I found that his work necessitated constant contact with an oil which covered the surface of steel sheets which he handled. He has since reported to me that all the other men engaged in the same duties had experienced the same type of sensory loss. In my patient, sensation returned in the toes promptly after he substituted intact shoes for the ones he had been wearing. In the fingers a restoration of sensibility has also occurred since he has been avoiding contact with the oil as much as practicable. The oil involved is called solvac No. 1534 manufactured by the Socony-Vacuum Oil Company, Inc., of Chicago. What constituent of the oil may be responsible for this effect? Can any permanent impairment result from the prolonged and intimate contact necessitated by this man's duties?

Benjamin B. Cohen, M.D., East Chicago, Ind.

ANSWER.—This type of oil represents chiefly mineral oil, sulfonated naphthenic acid, with a content of from 1 to 1.5 per cent phenol. Ordinarily this is diluted with water and is applied in the quenching of hot steel sheets. Tens of thousands of workers daily handle sheets that have been treated in this manner without any known untoward results. Obviously, much of the water is evaporated so that the residue on the sheet may approximate the original consistency. If the tingling mentioned is to be associated with work as a cause, this possibly is related to the phenolic content. Phenol is well known as a source of minor skin anesthesia. This query implies that the toes are numb only when the shoes worn are not "intact." In this case spillage followed by evaporation might account for the numbness of the toes. It is not known that the addition of phenol serves any useful industrial purpose and thus possibly might be omitted. At this time various industrial substances contain ingredients for no other purpose than to give individuality to the trade preparation.

TETANUS AND INSECT BITES OR STINGS

To the Editor:—Is it advisable to give tetanus antitoxin for bee stings or stings or bites of other insects? I cannot find anything on this matter and wonder if any cases of tetanus have been reported from such sources. Tetanus is prevalent in this locality.

Garland McPherson, M.D., Itasca, Texas.

ANSWER.—Although it is stated that tetanus has developed following insect bites, particularly when the bites were on the lower extremities and had become contaminated by dirt, the chances of such infections occurring are usually slight. It should be remembered that tetanus bacilli usually are unable to grow except in the presence of devitalized tissue and a considerably reduced oxygen tension. Insect bites and stings do not usually cause much destruction of tissue unless the wounds become secondarily infected. If, however, the bites are likely to be contaminated by dirt containing horse manure, are likely to be given in order to play safe. It might antitoxin might well be given in order to avoid sensitization be well to give bovine antitoxin in order to avoid sensitization to horse serum and to minimize the chances of serum disease, particularly in persons who have received horse serum before. No general rule should be followed with regard to the use of antitoxic serum for minor wounds, and individual circumstances must determine the matter.

RELIEF OF URTICARIA DURING PREGNANCY

To the Editor:—A woman aged 25, the mother of one child, pregnant since Oct. 25, 1938, gives the following history: She has always been well so far as she is aware except for violent attacks of what has been called asthma. These attacks come only at the menstrual period and are relieved by epinephrine or similar medication. She insists that during pregnancy she is absolutely free of attacks. She is so concerned that she asked whether the ovaries could not be removed, thus ending menstruation. She had thought this out for herself. I have seen her in the attacks previous to this pregnancy and they are truly severe. I am reminded of a similar case which came under my care more than thirty years ago. The patient would have an attack of giant urticaria with each period, but during pregnancy she would be entirely free of them. I saw her through two pregnancies and can vouch for the correctness of the history, as I also saw her in many attacks of urticaria. Now what, if any, light can be given as to the cause and the possible treatment? M.D., Iowa.

ANSWER:—The fact that a patient may have asthma only at the menstrual period and is free from asthma during pregnancy is one that has been known for many years. In some cases of urticaria also a similar condition exists. It is difficult to give the reason for this phenomenon. Undoubtedly the ovaries play a part, but just what part has not been determined. Many men have recognized this situation and have given injections of extracts of whole ovary or of a part of the ovary or some estrogenic preparation and have obtained good results with lessening of the attacks of asthma or urticaria.

On the other hand, it is also known that there are patients who get asthma or urticaria only during pregnancy. These conflicting situations add to the difficulties regarding explanation and treatment.

POSTSURGICAL TREATMENT OF OVARIAN CARCINOMA

To the Editor:—Recently I operated on a young unmarried woman aged 22 for an ovarian cyst. The cyst was about the size of an egg and had all the appearances of a hemorrhagic cyst. The cyst was removed without being broken. No other organs were removed except the appendix. The pathologic report was cystadenoma with carcinomatous degeneration. The majority of my colleagues were of the opinion that no further intervention should be attempted. The roentgenologist was of the opinion that roentgen therapy of adenocarcinoma of the ovaries is of little success and would make an invalid of the patient. Would you kindly advise what further should be done, especially concerning roentgen therapy. M.D., Ohio.

ANSWER:—When one ovary is the seat of a pseudomucinous cyst, the opposite ovary may be preserved if it is grossly normal. These tumors are rarely bilateral. Papillary serous cysts are often bilateral; consequently a secondary tumor frequently develops in the opposite ovary, even after complete removal of the other ovary. In the presence of definitely malignant papillary carcinoma, removal of both ovaries, tubes and the uterus is indicated, regardless of the gross appearance of the opposite ovary. The extent of the surgical operation that should be performed for an ovarian tumor, therefore, depends on the exact diagnosis and classification of the lesion.

There does not appear to be any indication for roentgen therapy in this case. Either the patient requires no further treatment or a second surgical operation should be performed. The choice between these two procedures must depend on an exact gross and microscopic diagnosis of the lesion removed as well as on the operative appearances in regard to the opposite ovary and the uterus at the time of the operation.

DEVIL'S CLUB AND DIABETES

To the Editor:—I should like some information regarding the status of devil's club in the treatment of diabetes. There is considerable interest in this part of the country regarding it. Is there something to it? E. K. Stimpson, M.D., Bellingham, Wash.

ANSWER:—As far as is known, there has been no published article concerning the extract of "devil's club" since that of Large and Brocklesby in the July 1938 issue of the *Canadian Medical Association Journal*. At present, at least, such extracts have no recognized place in the treatment of diabetes, and these authors made no therapeutic claims for it in their original article.

It has been reported that from other plants and green vegetables extracts can be made which, when administered by mouth, lower the blood sugar. A report on the "Effects of Cabbage Extracts on Carbohydrate Metabolism" was made by MacDonald and Wislicki in the *Journal of Physiology* (94:249 [Nov. 14] 1938). It is interesting that not only hypoglycemic but hyperglycemic extracts have been made from plants.

In this connection it is wise to call attention to the difference between the blood sugar lowering action of a given substance

and its ability to exert the metabolic influences known to follow the injection of insulin. Thus guanidine derivatives, such as synthalin, in exerting slight hypoglycemic action, may produce actual toxic effects, especially on the liver and kidneys.

FLY SPRAYS

To the Editor:—Please let me know what substitute can be used for an ordinary fly spray when one member of the household is sensitive to pyrethrum. M.D., California.

ANSWER:—There are three constituents that are mainly employed in the preparation of fly sprays: pyrethrum, rotenone and the aliphatic thiocyanate known as lethane. Of the latter two, lethane is probably more satisfactory than rotenone; frequently mixtures of the two are used in commercial preparations of fly spray. Lethane is manufactured by Rohm & Haas Company, Bristol, Pa., from whom a list of the commercial brands of fly spray containing their product can probably be obtained.

THIAMIN CHLORIDE IN BERIBERI

To the Editor:—A patient has complete paralysis of the arms, legs and vocal cords from beriberi. What are the prospects for regeneration of the nerves under thiamin chloride therapy? In what way is the nervous system affected in beriberi other than degeneration of the myelin sheaths, shrinking of the neurons and disappearance of the Nissl granules? L. A. Crowell Jr., M.D., Lincolnton, N. C.

ANSWER:—This case of "complete paralysis of the arms, legs and vocal cords from beriberi" is of an unusual type. It would aid in arriving at a satisfactory basis for prognosis to administer 50 mg. of thiamin chloride in sterile physiologic solution of sodium chloride twice a day for ten days. If at the end of that period there is no improvement, it is unlikely that vitamin B₁ will produce a change. One must then consider a possible error in diagnosis or the fact that the changes which have occurred are no longer reversible (a rare condition). The great majority of patients with beriberi respond dramatically to injections of adequate amounts of thiamin chloride.

Details of involvement of the nervous system and of therapy with vitamin B₁ can be found in Williams and Spies' book "Vitamin B₁ and Its Use in Medicine."

CAMPHORATED PHENOL

To the Editor:—Can you supply me with a formula by which phenol can be rendered less irritating for local use? Thomas M. Stewart, M.D., Cincinnati.

ANSWER:—Camphorated phenol N. F. VI, with the formula phenol 30 Gm., camphor 60 Gm. and sufficient liquid petrolatum to make 100 cc., is a preparation having a high antiseptic value with less caustic properties than phenol.

"GOLD INJECTIONS AND COLITIS"

To the Editor:—In The Journal April 22 there is a statement concerning gold injections and colitis in reply to a query from M.D., Connecticut. I have recently observed a case of profound colitis beginning with the administration of gold sodium thiosulfate for lupus erythematosus. The patient was severely ill for a long period thereafter but has now recovered. It has occurred to me that I should send you a report of my case:

Mrs. A. H. G., aged 33, had had normal digestive health prior to the onset of the difficulties to be mentioned. In 1936 lupus erythematosus developed. A general study revealed no evidence of tuberculosis. Following local treatment the lupus disappeared but it recurred in the summer of 1938. A physician thereafter gave five injections of gold sodium thiosulfate. Prior to the fifth injection, diarrhea and abdominal pain developed. The fifth injection was given Sept. 28, 1938. Following this, diarrhea became profound and the patient passed blood. She then entered the New York Post Graduate Hospital, where studies of stools failed to reveal *Endamoeba histolytica* or the bacteria of dysentery. She entered the Emergency Hospital in Washington, D. C., November 20 and remained in this hospital until Jan. 16, 1939. During this period she was profoundly ill and over the first five weeks of her stay she had as many as forty stools a day, with passage of blood and mucus. She became so ill that it appeared that she would die. Repetition of studies of stools gave results similar to those obtained at the New York Post Graduate Hospital. X-ray examination by barium sulfate enema November 29 showed "marked spasticity of the entire colon, with irregularity in the region of the cecum and terminal ileum." A repetition of the barium enema Feb. 13, 1939, showed "striking improvement in the bowel." The patient began to improve during the sixth week of her hospital stay and thereafter gradually regained weight and had fewer movements. Her weight had dropped to 69 pounds (31 Kg.) when she was first able to be weighed. Since then, the patient has gradually recovered and now has essentially normal movements. Her weight had come up to 111 pounds (50 Kg.) by May 28. A proctoscopic examination done May 8 revealed normal mucosa. At no time was there evidence of injury to the bone marrow in this case. M. W. Perry, M.D., Washington, D. C.

Medical Examinations and Licensure

COMING EXAMINATIONS

NATIONAL BOARD OF MEDICAL EXAMINERS SPECIAL BOARDS

Examinations of the National Board of Medical Examiners and Special Boards were published in THE JOURNAL, August 26, page 880.

STATE AND TERRITORIAL BOARDS

ALABAMA: Montgomery, June 18-20. Sec., Dr. J. N. Baker, 519 Dexter Ave., Montgomery.

ALASKA: Juneau, Sept. 12. Sec., Dr. W. W. Council, Box 561, Juneau.

ARIZONA: *Basic Science*. Tucson, Sept. 19. Sec., Dr. Robert L. Nugent, Science Hall, University of Arizona, Tucson. *Medical*. Phoenix, Oct. 3-4. Sec., Dr. J. H. Patterson, 826 Security Bldg., Phoenix.

ARKANSAS: *Basic Science*. Little Rock, Oct. 23. Sec., Mr. Louis E. Gebauer, 701 Main St., Little Rock. *Medical (Regular)*. Little Rock, Nov. 9-10. Sec., Dr. D. L. Owens, Harrison. *Medical (Eclectic)*. Little Rock, Nov. 9-10. Sec., Dr. Clarence H. Young, 1415 Main St., Little Rock.

CALIFORNIA: *Written examination*. Sacramento, Oct. 16-19. *Oral examination* (required when reciprocity application is based on a state certificate or license issued ten or more years before filing application in California). San Francisco, Nov. 15. Sec., Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento.

COLORADO: *Endorsement*. Denver, Oct. 4-6. Sec., Dr. Harvey W. Snyder, 831

CONNECTICUT: *Basic Science*. New Haven license examination. Address State Board of Station, New Haven. *Medical (Regular)*. Ex 14-15. *Endorsement*. Hartford, Nov. 28. Sec., Dr. Thomas P. Murdock, 147 W. Main St., Meriden. *Medical (Homoeopathic)*. Derby, Nov. 14-15. Sec., Dr. Joseph H. Evans, 1488 Chapel St., New Haven.

DELAWARE: *Examination*. Dover, July 9-11. *Reciprocity*. Dover, July 16. Sec., Medical Council of Delaware, Dr. Joseph S. McDaniel, 229 S. State St., Dover.

DISTRICT OF COLUMBIA: *Basic Science*. Washington, Oct. 23-24. *Medical*. Washington, Nov. 13-14. *Formal application* and supporting data must be received before Oct. 1. Sec., Commission on Licensure, Dr. George C. Ruhland, 203 District Bldg., Washington.

FLORIDA: Jacksonville, Nov. 13-14. Sec., Dr. William M. Rowlett, Box 786, Tampa.

GEORGIA: Atlanta, Oct. 10-11. Joint-Sec., State Examining Boards, Mr. R. C. Coleman, 111 State Capitol, Atlanta.

HAWAII: Honolulu, Oct. 9-12. Sec., Dr. James A. Morgan, 48 Young Bldg., Honolulu.

IDHO: Boise, Oct. 3-4. Dir., Bureau of Occupational License, Mr. H. B. Whittlesey, State Capitol Bldg., Boise.

ILLINOIS: Chicago, Oct. 17-19. Superintendent of Registration, Department of Registration and Education, Mr. Homer J. Byrd, Springfield.

INDIANA: Indianapolis, June 18-20. Sec., Board of Medical Registration and Examination, Dr. J. W. Bowers, 301 State House, Indianapolis.

IOWA: *Basic Science*. Des Moines, Oct. 10. Dir., Division of Licensure and Registration, Mr. H. W. Grefe, State Department of Health, Ca

Dec. 5-7. Sec., State Board of Health, Dr. Third St. Louisville.

MAINE: Portland, Nov. 14-15. Sec., Board of Registration of Medicine, Dr. Adam P. Leighton, 192 State St., Portland.

MARYLAND: *Regular*. Baltimore, Dec. 12-15. Sec., Dr. John T. O'Mara, 1215 Cathedral St., Baltimore. *Homoeopathic*. Baltimore, Dec. 12-13. Sec., Dr. John A. Evans, 612 W. 40th St., Baltimore.

MASSACHUSETTS: Boston, Nov. 14-16. Sec., Board of Registration in Medicine, Dr. Stephen Rushmore, 113-F State House, Boston.

MICHIGAN: Lansing, Oct. 11-13. Sec., Board of Registration in Medicine, Dr. J. Earl McIntyre, 100 W. Allegan St., Lansing.

MINNESOTA: *Basic Science*. Minneapolis, Oct. 3-4. Sec., Dr. J. Charnley McKinley, 126 Millard Hall, University of Minnesota, Minneapolis. *Medical*. Minneapolis, Oct. 17-19. Sec., Dr. Julian F. Du Bois, 350 St. Peter St., St. Paul.

MISSISSIPPI: *Reciprocity*. Jackson, December. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson.

MONTANA: *Reciprocity*. Helena, Oct. 2. *Examination*. Helena, Oct. 3-4. Sec., Dr. S. A. Cooney, 216 Power Block, Helena.

NEBRASKA: *Basic Science*. Lincoln, Oct. 3-4. Dir., Bureau of Examining Boards, Mrs. Clark Perkins, 1009 State Capitol Bldg., Lincoln.

NEVADA: *Written examination and reciprocity with oral examination*. Carson City, Nov. 6. Sec., Dr. John E. Worden, 311 W. Robinson St., Carson City.

NEW HAMPSHIRE: Concord, Sept. 14-15. Sec., Board of Registration in Medicine, Dr. T. P. Burroughs, State House, Concord.

NEW JERSEY: Trenton, Oct. 17-18. Sec., Dr. Earl S. Hallinger, 28 W. State St., Trenton.

NEW MEXICO: Santa Fe, Oct. 9-10. Sec., Dr. Le Grand Ward, 135 Sena Plaza, Santa Fe.

NEW YORK: Albany, Buffalo, New York and Syracuse, Sept. 18-21. Chief, Bureau of Professional Examinations, Mr. Herbert J. Hamilton, 315 Education Bldg., Albany.

NORTH CAROLINA: *Reciprocity and Endorsement*. Raleigh, Dec. 11. Sec., Dr. W. D. James, Hamlet.

NORTH DAKOTA: Grand Forks, Jan. 2-5. Sec., Dr. G. M. Williamson, 415 S. Third St., Grand Forks.

OKLAHOMA: *Basic Science*. Oklahoma City, Nov. 6. Sec. of State, Hon. C. C. Childress, State Capitol, Oklahoma City. *Medical*. Oklahoma City, Dec. 13. Sec., Dr. James D. Osborn, Jr., Frederick.

OREGON: *Basic Science*. Portland, Oct. 28. Sec., State Board of Higher Education, Mr. Charles D. Byrne, University of Oregon, Eugene.

PENNSYLVANIA: Philadelphia, January. Dir., Bureau of Professional Licensing, Dr. James A. Newpher, Department of Public Instruction, 358 Education Bldg., Harrisburg.

PUERTO RICO: Santurce, Sept. 5. Sec., Dr. O. Costa Mandry, Box 3854, Santurce.

RHODE ISLAND: Providence, Oct. 5-6. Sec., Board of Examiners in Medicine, Dr. Robert M. Lord, 122 Waterman Ave., Providence.

SOUTH CAROLINA: Columbia, Nov. 14. Sec., Dr. A. Earle Boozer, 505 Saluda Ave., Columbia.

SOUTH DAKOTA: Pierre, Jan. 16-17. Dir., Medical Licensure, Dr. G. J. Van Heuvelen, State Board of Health, Pierre.

TENNESSEE: Memphis, Sept. 27-28. Sec., Dr. H. W. Qualls, 130 Madison Ave., Memphis.

TEXAS: Austin, Nov. 20-22. Sec., Dr. T. J. Crowe, 918-19-20 Mercantile Bldg., Dallas.

VERMONT: Burlington, Feb. 13-15. Sec., Board of Medical Registration, Dr. W. Scott Nay, Underhill.

VIRGINIA: Richmond, Dec. 13. Sec., Dr. J. W. Preston, 301 Franklin Road, Roanoke.

WEST VIRGINIA: Fairmont, Nov. 6-8. Sec., Public Health Council, Dr. Arthur E. McClue, State Capitol, Charleston.

WISCONSIN: *Basic Science*. Madison, Sept. 23. Sec., Professor Robert N. Bauer, 3414 W. Wisconsin Ave., Milwaukee. *Medical Reciprocity*. Milwaukee, Sept. 14. *Examination*. Madison, Jan. 9-11. Sec., Dr. Henry J. Gramling, 507 Mariner Tower, Milwaukee.

WYOMING: Cheyenne, October. Sec., Dr. M. C. Keith, Capitol Bldg., Cheyenne.

Maine July Examination

Dr. Adam P. Leighton, secretary, Maine Board of Registration of Medicine, reports the written examination held at Augusta, July 11-12, 1939. The examination covered ten subjects and included 100 questions. An average of 75 per cent was required to pass. Twenty-one candidates were examined, nineteen of whom passed and two failed. Five physicians were licensed by reciprocity and three physicians were licensed by endorsement after an oral examination. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Yale University School of Medicine.....	(1939)	79	
Georgetown University School of Medicine.....	(1938)	82	
Boston University School of Medicine.....	(1936) 79, (1939)	82, 82

Book Notices

Pediatric Symptomatology and Differential Diagnosis. By Sanford Blum, A.B., M.S., M.D., Head of Department of Pediatrics and Director of the Research Laboratory, San Francisco Polytechnic and Post Graduate School, San Francisco. Cloth. Price, \$5. Pp. 500, with 29 illustrations including one color plate. Philadelphia: F. A. Davis Company, 1938.

It was inevitable that sooner or later some one would write a book on the differential diagnosis of children's diseases. The author has done this by emphasizing the symptomatology and diagnostic features of the various conditions. No attempt was made to discuss the etiology, pathology and therapy. Each subject has a general plan of discussion, beginning with the definition, terminology and enumeration of the principal features of the disease, followed by a description of the symptoms, and concluding with a detailed differential diagnosis which differentiates the condition from conditions with which it is likely to be confused. The book is complete. In fact the repetition that is necessary in the differential diagnoses could possibly have been omitted, but it does not detract from the value of the book as a reference guide. The sections on the exanthems and acute infectious diseases are decidedly helpful. The book should be of aid to the clinician, the practitioner and the student.

William B. Wherry, Bacteriologist. By Martin Fischer. Cloth. Price, \$4. Pp. 293, with illustrations. Springfield, Illinois & Baltimore: Charles C. Thomas, 1938.

The physiologist Martin Fischer has rendered a real service to American medicine by depicting in a most attractive way the interesting life of the bacteriologist Dr. William B. Wherry, who was his close and lifelong friend. From every page emanates their mutual intimacy, as well as the sincere and deep affection which for so many years each felt for the other. This sustains the interest of the reader and is a fascinating feature of the book.

The volume is rich in factual data concerning bacteriologic and medical contributions of the past generation. It has therefore the significance of an important chapter in the formative history of the science of bacteriology in the United States.

Wherry's life was in many ways unusual and at times approached the dramatic. Born in India in 1874 into a cultured missionary family, he came to Chicago's west side early in life. His college years were spent at Washington and Jefferson College, of which his father was an alumnus. His medical education was received at Rush Medical College at a time when it was dominated by a group of medical masters, from whom he received both information and inspiration. One of these masters was Ludvig Hektoen, into whose laboratory Wherry was admitted early in his medical career and by whose influence the trend of his life was to a large degree determined.

He obtained his M.D. in 1901 and next year was on his way to the Philippines. There, in the government health laboratories at Manila, he was confronted at once by a host of the great disease problems of the world—plague, cholera, dysentery, leprosy, tropical parasites—all of which presented rare opportunities for clinical, pathologic and bacteriologic studies. Soon his pen became active, and for the remainder of his life he was a consistent contributor to medical literature.

In 1905 he left the Philippines to return to the United States, westward through India and Europe. He visited his parents in India, where he lingered long enough to observe at first hand the horrible ravages of bubonic plague and other tropical diseases.

After a profitable sojourn in the laboratories of Europe he reached the United States, to learn of an interesting problem awaiting solution in Montana. This had to do with the poisonous effects of the fumes of the copper smelters on live stock. Accepting this opportunity, he had for a time a profitable experience in the domain of animal pathology. On the side, as it were, he organized there a local health laboratory, and there too he first met Theobald Smith.

In 1907 he went to Oakland, Calif., as professor of parasitology on the staff of Oakland College of Medicine. With his past experience in the Philippines he was eminently fitted to play while here a leading part in the campaign against bubonic

plague then raging in San Francisco. For two years he participated in the dramatic incidents on the Pacific Coast at the very time when plague was gaining a permanent endemic foothold in this country. It was during these investigations that he first recognized plague in the ground squirrels of that vicinity.

After this exciting period he accepted an offer of a professorship from the reorganized Ohio-Miami Medical College of the University of Cincinnati. Beginning his work there under many handicaps and with limited facilities, he soon became a leading factor in the rapid development of this important medical center. It was in this institution that he finally found his life's satisfactions realized and continued to teach and study during the remainder of his career.

Dr. Wherry's interests in the special field of pathogenic bacteriology were broad and comprehensive. Early he contributed much to the morphology and physiology of bacteria as well as to the specific etiology and knowledge of the transmission of disease. In later years he became interested in the preventive problems of infectious diseases, including immunity, vaccines, serums and antiseptics. Much of his work was closely associated with clinical medicine. His De Lamar Lecture given at Johns Hopkins University in 1931 was a critical study entitled "Hypersensitivity to Bacterial Proteins and Its Role in Susceptibility and Immunity." In this, as the author states, appears the "most succinct statement of his scientific philosophy."

Dr. Wherry died in 1936. His bibliography as published at the end of the volume comprises eighty-two papers and extends in time from 1899 to 1935. These papers were issued with a high degree of regularity and appeared in the best journals of the period. A striking characteristic of his contributions was his terse, concise style. A few pages as a rule was sufficient for him to present his most noteworthy researches.

The book is not only well written but well arranged and well printed. The paper is of fine texture and the cover a pleasing blue. It is a worthy contribution and one that will be appreciated by Dr. Wherry's numerous friends and associates.

Behandlung der Knochen- und Gelenktuberkulose nach den Erfahrungen von Hohenlychen vom November 1933 bis 1938. Unter Mitarbeit von Dr. Richard Schulze, Dr. Ludwig Stumpfegger und Dr. Wilhelm Bayer. Herausgegeben von O. Univ.-Prof. Dr. Karl Gebhardt, Chefarzt der Heilanstalten Hohenlychen und Leiter des Medizinischen Instituts der Reichsakademie für Leibesübungen in Berlin. Paper. Price, 5.40 marks. Pp. 62, with 48 illustrations. Leipzig: Johann Ambrosius Barth, 1939.

The authors present a critical review of 497 cases treated between November 1933 and November 1938. The rate of sedimentation was found to be a useful indicator of the activity of the process and was taken every four weeks. A low lymphocyte count with absence of eosinophils in the presence of a leukocytosis was considered an unfavorable sign. The Pirquet reaction was used in children but not in adults. Roentgenograms were of little use until after three months of the onset of symptoms. Biopsy and guinea pig inoculation were used in doubtful cases. The importance of general treatment and exposure to sun is stressed. Immobilization in generous casts is advocated, double hip spicas for knees and posterior shells for spines. The healing of synovial tuberculosis with good motion is reported. Deformities are corrected with stretching and casts or by osteotomy. Pott's disease is treated by recumbency in plaster until bony healing is definite. This occurs in about two and one-half years in favorable cases. Operative treatment is little used in children. In adults, amputation, excision of foci near a joint, circumscribed foci within joints and joint resections are indicated according to the location and progress of the lesion. Surgery is done with the electric "knife." The authors do not consider trauma of primary importance in the development of the tuberculous lesion. Of the 497 patients, 337 were adults and 160 children; 229 were cured and twenty-one died. The results of surgery were good and accompanied with a distinct shortening of time of supervision. Of the total of 497 patients, 81 per cent (403) had received previous treatment under a wrong diagnosis. The need of education and economic rehabilitation is emphasized. The authors present a critical analysis of a large series of cases treated by nonoperative and operative methods. The text is illustrated with many photographs and reproductions of roentgenograms.

Diets of Families of Employed Wage Earners and Clerical Workers in Cities. By Hazel K. Stiebeling, Senior Food Economist, and Esther F. Philpard, Associate Economist, Economics Division, Bureau of Home Economics. United States Department of Agriculture, Circular 507. Paper. Price, 15 cents. Pp. 141, with 8 illustrations. Washington, D. C.: Supt. of Doc., Government Printing Office, 1939.

This bulletin presents the results of a study of the food consumption of 4,000 families of wage earners and clerical workers in forty-three industrial centers in eight major geographic regions in the United States. The data were obtained from food records kept by the families for one week. The records have been analyzed to show the expenditures for food, the quantities of various foodstuffs purchased and the adequacy of the diets available for consumption. The data are classified by region, race of family and food expenditure level. Unfortunately no totals are given in the tables, and if information regarding the food consumption is desired for all people rather than for the various expenditure levels it must be computed from the data which are given in the tables. In using the results of this study it is important to bear in mind several limitations which are pointed out by the authors: (1) The sample is a somewhat biased one, owing to the necessity of choosing families that would cooperate by keeping records, (2) the amounts of foodstuffs represent merely the total available for consumption, as no allowance was made for waste, and (3) the figures for vitamins, especially C and B₁, are probably higher than the amounts actually obtained, because no allowance was made for losses in cooking. Interpretation of the dietary deficiencies found must also be made in the light of the standards for the various dietary essentials that were employed. Standards are as yet largely empirical and some of those used in this report, in particular for vitamins B₁ and A, are higher than many workers would consider had yet been established. The study as a whole represents the first significant approach to a nationwide study of the adequacy of the diets consumed by people in the United States and as such it will be a valuable compendium of information for all concerned with the problem of nutrition and public health.

Clinical Pediatrics (The Baby). Edited by W. R. F. Collis, M.A., M.D., F.R.C.P., *Pediatrician Rotunda Hospital, Dublin.* With a foreword by Andrew H. Davidson, M.D., F.R.C.P.I., F.C.O.G., Master of the Rotunda Hospital, Dublin. Cloth. Price, 21s. Pp. 460, with 106 illustrations. London: William Heinemann, 1938.

The author with the aid of several collaborators on specialized subjects has written an extremely practical book on the baby. A definite attempt was made to limit the material discussed to the period of infancy and, although this plan has been faithfully adhered to, many of the discussions concern conditions that affect the older child. The book covers the field of neonatal care, infant feeding, congenital defects, infectious diseases and general pediatric subjects. The chapters on celiac disease and tuberculosis are well treated. Emphasis has been laid on the description of congenital defects and the time at which treatment should be instituted. Such subjects as pyloric stenosis, cleft palate, harelip and ophthalmia neonatorum have been treated in detail. This book should be of value to the general practitioner, the obstetrician, the medical student and the pediatrician who wants a rapid reference work at hand.

Teachable Moments: A New Approach to Health. By Jay B. Nash, Ph.D., Professor of Education, School of Education, New York University, New York. Cloth. Price, \$1.50. Pp. 243. New York: A. S. Barnes & Company, 1938.

The author intended this book for those who have definite responsibilities regarding the health of school children. This includes the educational administrators, the teachers and the parents. There are ten chapters that present discussion on "What Is Health?" "The Stroke-Glide of the Human Engine," "Teachable Moments," "Truths and Part-Truths About Health," to the final ones on "Schools Should Be More Than Text-books," and "What the Community Might Do If—." There are many errors of fact. The author speaks of the thymus gland as an important regulator in the first two or three years of life. He announces its function as being particularly in connection with the growth of the heart, the hair and the respiratory system. The definite function of this gland has not as yet been determined. According to authorities the thymus is concerned with growth, calcium metabolism, nutri-

tion and blood formation. There is no evidence that the gland, when removed, produces any detectable alteration in hair. In discussing foods the author speaks of vitamin C as being particularly important in preventing tooth decay. "Milk is especially rich in this vitamin." This will be of interest to most nutritionists, since even raw milk is not especially rich in vitamin C. The author also states that modern canning processes destroy vitamins. This is no longer true, since modern canning processes are designed to retain the vitamins to the highest extent consistent with safe methods of processing and many canned foods are excellent sources of the various vitamins. Canned citrus juices and tomato juice are recognized as excellent sources of vitamin C. Also vitamin C is not the most important vitamin in preventing tooth decay. The author, in his discussion on sleep as an essential for good health, states that for children whose hours of sleep are reduced below normal the stage is set for malnutrition and tuberculosis. Tuberculosis does not develop unless infection is present.

The author holds out for protective laws that will make mandatory the acceptance of immunization and vaccination. He states that these services should be free and convenient for everybody. Free services, including corrective dentistry, should be made available to all children everywhere. He speaks especially of the great benefits that would result for the people if diagnostic centers under the federal government were made available to every one. In the same paragraph he decries the present condition in which parents must depend on their own physician for medical services. Several times the author speaks of school attendance in the modern school encouraging malnutrition and bringing about a "decrease in red blood corpuscles." This statement is fallacious. Anemia is not produced by school attendance per se. A misstatement by the author deals with a discussion of the episode wherein a number of persons died as a result of the taking of an elixir of sulfanilamide. He states that the person responsible was not punished but was allowed to go free by merely stating that he "broke no law." The fact is, the heaviest punishment possible was dealt out in this instance.

Throughout the entire book the author argues for some form of medical practice entirely controlled by the government. In advancing the argument for free medical service and a change from the present medical care by private physicians he lists only the advocates for plans not sponsored by the medical profession itself. He states that he is inadequately covering both sides of a controversy and then proceeds to give only one side and does not even mention that a great amount of opposition has grown up against these various procedures. The author is either not acquainted with the many sources for obtaining information about health, including consumer education, available to every one today, or else he chooses to ignore them.

Diet and Ill-Health in the Forest Country of the Gold Coast. By F. M. Purcell, M.D., M.R.C.P., D.T.M. & H., Colonial Medical Service, Gold Coast. Cloth. Price, 7s. 6d. Pp. 77, with 62 illustrations. London: H. K. Lewis & Co., Ltd., 1939.

This brochure discusses some of the nutritional problems of the people of Akim, situated in the forest toward the south of the Gold Coast colony, Africa, and describes cases of malnutrition observed among children attending the dispensary at Oda, the capital, during 1935 and 1936, the clinical notes of the author being illustrated by a number of photographs. A table is given showing the nutritive values of foods available in western Akim (but the estimates are made from published data and not from actual analyses). Information collected from mothers regarding their own food and that of their children has been tabulated to show roughly the types and amounts of foods consumed. It is estimated that the nursing mothers ingest at most from 30 to 50 Gm. of protein of poor quality, and the vitamin and mineral intake is undoubtedly low. In brief, the diet is described as a borderline or "dangerous diet." Breast milk is often of poor quality. The case is cited of a baby fed from birth canned milk and orange juice who "differed from all other babies in that he was plump, robust, and constantly cheerful, with clear laughing eyes, and a skin of fine texture." A plan for a better diet has been prepared as a guide for village school teachers, with liberal portions of beans, ground nuts, green leaves and

tomatoes, fruit, palm oil, one egg three times a week and 2 ounces of canned milk four times a week. It is pointed out that improvement of the diet is possible for many of the inhabitants with better selection and improved methods of cooking vegetables. Instruction in nutrition in all schools is strongly advised. A nutrition committee has been formed and the need of a full time dietetics officer is pointed out.

Clinical Gastroenterology. By Horace Wendell Soper, M.D., F.A.C.P. Cloth. Price, \$6. Pp. 314, with 212 illustrations. St. Louis: C. V. Mosby Company, 1939.

This book is primarily a review of the author's clinical experiences in the treatment of diseases of the gastrointestinal tract. The personal touch is well emphasized in his instructions to patients. His methods of collecting laboratory data are peculiar to his own office practice. The text is amply illustrated. However, many of the x-ray films are obsolete, as evidenced by the presence of a ring to denote the position of the umbilicus on the plate. These, as the author does not state, are some of the older films of the late R. Walter Mills. The book is wanting in the newer and more modern scientific approach to the problems of gastro-enterology. It is of little value to the real student in gastro-enterology today and resembles a cursory "brush-up course" as given in some of the mediocre schools of graduate work. The book, as a whole, is simply and clearly written.

Applications médicales du nouveau Codex et prescription des substances vénéneuses. Par René Hazard, professeur à la Faculté de médecine de Paris. Paper. Price, 18 francs. Pp. 95. Paris: Masson & Co, 1939.

This concise monograph summarizes for the physician the French pharmacopeial codex of 1937, which became official in April 1938. The French Codex comprises two volumes: the first, containing the laws and regulations governing the practice of pharmacy, the prescription and sale of poisons, and statements of general interest; the second, the codex proper, containing descriptions, chemical and biologic assays and methods of preparation of the various official substances and mixtures. Professor Hazard discusses omissions, additions and modifications in the new edition of the codex, with special emphasis on the regulations concerning the possession, prescription and sale of nearly 260 narcotics. The book should be of value to those physicians who have an interest in the international ramifications of their pharmacopeia.

The New-Born Infant: A Manual of Obstetrical Pediatrics. By Emerson L. Stone, M.D., Associate Clinical Professor of Obstetrics and Gynecology, School of Medicine, Yale University, New Haven, Connecticut. Second edition. Cloth. Price, \$3. Pp. 291. Philadelphia: Lea & Febiger, 1938.

The mortality rate for infants under 1 year of age in the United States has declined steadily during the last several decades. The mortality rates for infants under 2 weeks of age and during the first day of life have not kept pace. There is consequently a need for careful study of the conditions affecting the newborn infant. It is the attempt of this book to correlate and arrange in an orderly fashion the data concerning the newborn with particular emphasis on the obstetrician's point of view and responsibility. The book succeeds admirably in its purpose. The early chapters deal with the immediate care of the newborn, physiology and development, nursing care and feeding. Later chapters are concerned with the dietary disorders, birth injuries, infections and other disorders of the newborn infant. The references to the periodical literature are profuse and add greatly to the value of the book. All those interested in infant mortality and in the care of infants should find this book extremely useful.

Memorialia Herman Boerhaave. Optimi Medici. Cloth. Price, 1.90 florins. Pp. 133, with 14 illustrations. Haarlem: De Erven F. Bohn N. V., 1939.

This is a special printing (type reset) of the speeches delivered at the commemoration meeting of the two hundredth anniversary of the death of Herman Boerhaave, held at Leiden, the Netherlands, Sept. 23, 1938, which originally appeared in a special number of the *Nederlandsch tijdschrift voor geneeskunde*, Oct. 1, 1938, pp. 4777-4912. All the papers in Dutch have been translated into English, French or German. The papers of special interest to American readers are the scholarly account

by J. D. Comrie on the influence of Boerhaave in the early days of the medical school in Edinburgh, Henry E. Sigerist's discussion of Boerhaave's influence on American medicine and K. F. Wenckebach's article on Boerhaave's relations with the medical school at Vienna. J. F. Fulton has contributed a paper on the influence of Boerhaave's *Institutiones Medicae* on modern physiology. Edmund von Lippmann discusses his contribution to chemistry, and Isidore Fischer of Vienna deals with him as a clinician. The volume is well illustrated, and the papers form a fitting memorial to one of the greatest clinicians of all time.

Thorpe's Dictionary of Applied Chemistry. By Jocelyn Field Thorpe, C.B.E., D.Sc., F.R.S., Professor of Organic Chemistry and Director of Organic Laboratories, Imperial College of Science and Technology, London, and M. A. Whiteley, O.B.E., D.Sc., F.I.C., assisted by eminent contributors. Vol. II: Bi-Chemical Analysis. Fourth edition. Cloth. Price, \$25. Pp. 711, with illustrations. New York, Toronto & London: Longmans, Green & Co., 1938.

Widespread approval of earlier editions of Thorpe predicates interest in this second volume of the newly revised dictionary. Eighty-two contributors who have an intimate, practical knowledge of their subjects collaborated in its compilation. The authors continue the plan adopted in the first volume. Again they have inserted a number of monographs on fundamental topics and have retained carefully revised articles descriptive of leading industries. Information concerning chemical industries is based largely on British enterprise. The extensive section on chemical analysis (170 pages) contains nicely summarized material on qualitative and quantitative methods. Subtopics, such as colorimetric analysis, electrochemical analysis, gas analysis, microchemistry, physical methods in analysis, and special reactions, serve to round out the subject. Adequate references to the original literature indicate the thorough manner in which each subject is considered. The complete dictionary will serve as an interesting and authoritative source of chemical information for both the chemist and the nonchemist.

Nursing an Art and a Science. By Margaret A. Tracy, R.N., A.B., M.S., Director, Training School for Nurses, University of California, San Francisco, and Collaborators. Foreword by Annie Warburton Goodrich, M.A., (Sc.D.). Cloth. Price, \$3.25. Pp. 559, with 183 illustrations. St. Louis: C. V. Mosby Company, 1938.

This is a practical book portraying the training and teaching of nurses in a modern medical center. The meticulous care of the patient and the need for comfortable surroundings are emphasized. Bedside care and the preparation of patients for various examinations and tests to meet the demands of modern diagnostic medicine are included. Various routine tests which a nurse should know in order to carry out more accurately a physician's instructions are simply and intelligently described. The administration of drugs, the use of physical therapy, the preoperative and postoperative care and the complications that might retard convalescence are well covered. Not only is this book well worth while for nurses, but many a physician could learn from it innumerable methods of making patients more comfortable.

Play Therapy in Childhood. By C. H. Rogerson, M.D., M.R.C.P., D.P.M., Medical Director, The Cassel Hospital, Penshurst, Kent. Paper. Price, \$1.25. Pp. 64. New York & London: Oxford University Press, 1939.

Maladjustments in childhood have only recently attracted the attention of psychologists. The first psychologic clinic for children in the United States was formed in 1896. The work has developed and spread rapidly since that time, but the methods of treatment have not kept pace with the demands for therapy. Play therapy is one of the later additions to the methods employed for correction of maladjustment. In this book it is pointed out that it offers a twofold use: (1) as a means of treatment and (2) as a means of observation which will permit further understanding of the child. It is emphasized that play therapy is suitable only in certain cases of maladjustment and is not to be selected for children who might be expected to respond to simpler methods. The book begins with a historical summary, then follows with a description of clinical cases and ends with final conclusions and a short bibliography. Those who are interested in the psychologic maladjustments of childhood and their correction will find this book of interest.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Alcohol Allegedly Used for Procaine Hydrochloride (Novocain) as an Anesthetic.—The defendant physicians performed a herniotomy on the plaintiff in a hospital owned and operated by the defendant county. The operation was performed under a local anesthetic. Alleging that the defendants negligently used alcohol instead of novocain as an anesthetic, with resultant injury, the plaintiff sued the defendants. At the close of the plaintiff's evidence, the trial court sustained a motion filed by the defendants for a judgment of nonsuit, and the plaintiff appealed to the Supreme Court of Idaho.

The complaint charged that the defendants, instead of using a solution of novocain as a local anesthetic, "carelessly, negligently and recklessly furnished, supplied and injected into and under plaintiff's skin and the underlying tissues of the right inguinal area a solution of alcohol, which said alcohol destroyed the tissues or the natural resistance of the tissues of said area to infection and caused to be broken down or infected plaintiff's skin, subcutaneous tissues, muscles and nerves in said area and plaintiff's right thigh." But, said the Supreme Court, the plaintiff utterly failed to prove that alcohol was used instead of novocain as an anesthetic. The nurses who assisted in the operation all testified that novocain was used to produce the local anesthesia and that alcohol was used only to cleanse the surface prior to anesthetizing it. No one testified that alcohol was injected. The trial court properly sustained an objection to a hypothetical question presented to an expert witness which was intended to elicit from the witness the effect that the injection of a solution of alcohol instead of novocain would have on the area wherein the injection was made. There was at no time any proof that a solution of alcohol had been injected instead of novocain and, furthermore, the question assumed the proof of many facts that had not been suggested or covered by any evidence whatever.

The burden of proof was on the plaintiff, and it was not sufficient merely to show a possibility or raise a suspicion that the defendants may have been negligent. Some evidence is necessary, the court pointed out, either direct or circumstantial, to take a case to the jury, and there was none in this case. The judgment of the trial court was therefore affirmed. —*Evans v. Bannock County (Idaho)*, 83 P. (2d) 427.

Workmen's Compensation Acts: Insanity Attributed to Blow on Abdomen.—The plaintiff, a man aged 63, suffered an accidental injury arising out of and in the course of his employment as a male nurse for the State Psychopathic Hospital at Ann Arbor, Sept. 7, 1935. He was kicked on the abdomen by a patient. An operation disclosed a small tear in the lower part of the small intestine. The plaintiff remained in the general hospital for twenty days and was then transferred to a convalescent hospital. He returned home about four weeks after the injury. Compensation under the workmen's compensation act was paid to him until Sept. 19, 1936. On September 29, the defendants filed a petition to stop payment of compensation and, on May 20, 1938, the department of labor and industry denied the petition and the defendants appealed to the Supreme Court of Michigan.

The defendants contended that there was no competent evidence to support the finding of the department that the incapacity of the plaintiff for work was the result of the accident. The plaintiff, following the accident, never resumed employment of any kind. Subsequent to his return from the hospital he was committed to the Ypsilanti State Hospital as an insane patient. The department found that during the time that the plaintiff was employed by the defendant hospital and up to the time of his accidental injury he was mentally normal and in full possession of all his faculties. His disability dated from the accident and was a progressive development after that time.

The evidence supporting the plaintiff's claim was largely drawn from lay witnesses and was to the effect that prior to the injury the plaintiff was fully capable and competent to perform his duties as a male nurse. The defendants' evidence tended to show that subsequent to the injury the plaintiff had a generalized arteriosclerosis and elevated blood pressure and a deteriorated intellect and thinking ability and that this condition existed prior to the accident. In the opinion of the Supreme Court, however, the record sustained the finding of the department that the mental condition of the plaintiff dated from the accident and that the department had a right to rely on the testimony of the plaintiff and of lay witnesses in determining the duration of the condition. The action of the department in ordering that compensation be continued was therefore affirmed.—*Pretzer v. State Psychopathic Hospital (Mich.)*, 222 N. W. 213.

Paternity: Blood Grouping as Evidence of Nonpaternity.—Where, said the court of appeals of Ohio, Franklin County, a man is accused by an unmarried female of being the father of her unborn child and after the birth of the child an expert whose qualifications are not questioned makes a blood test of the blood of the mother, of the child and of the alleged father, the result of such test is competent evidence and may be introduced for whatever weight it may have to prove the nonpaternity of the alleged father.—*State v. Wright (Ohio)*, 17 N. E. (2d) 428.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1929 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Alabama State Medical Assn. Journal, Montgomery

9: 1-36 (July) 1939. Partial Index

Outbreak of Gastro-Enteritis Caused by Milk-Borne Staphylococci Producing an Enterotoxin. C. A. Abele and S. R. Damon, Montgomery.—p. 1.

Prevention and Treatment of Allergy. M. T. Davidson, Birmingham.—p. 4.

American Journal of Medical Sciences, Philadelphia

197: 741-888 (June) 1939

Exogenous Pernicious Anemia. G. Alsted, Copenhagen, Denmark.—p. 741.

Presence of Antipernicious Anemia Factor in Extract of Fetal Bovine Livers. H. S. Wigodsky, O. Richter and A. C. Ivy, Chicago.—p. 750.

*The Liver in Pellagra. V. P. Sydenstricker, H. L. Schmidt Jr., L. E. Geeslin and J. W. Weaver, Augusta, Ga.—p. 755.

Achlorhydria in Leukemias. Clara L. Davis and T. Fitz-Hugh Jr., Philadelphia.—p. 763.

Use of Vitamin B₁ in Rest Pain of Ischemic Origin. M. Naide, Philadelphia.—p. 766.

Drug Treatment of Angina Pectoris Due to Coronary Artery Disease. A. M. Master, H. L. Jaffe and S. Dack, New York.—p. 774.

*Necropsy Survey of Cardiovascular Syphilis, with Particular Reference to Its Decreasing Incidence. J. W. Welty, Philadelphia.—p. 782.

Treatment of Raynaud's Disease with Papaverine Intravenously. M. G. Mulinos, I. Shulman and I. Mufson, New York.—p. 793.

Sympathomimetic Stimulants in Acute Circulatory Failure of Phenol Shock. M. L. Tainter, A. W. Footer and H. Hanzlik, San Francisco.—p. 796.

*Intermittent Venous Compression in Treatment of Peripheral Vascular Disorders: Report on 103 Cases. D. W. Kramer, Philadelphia.—p. 808.

Herpes Zoster and Its Visceral Manifestations. E. S. Gais and R. H. Abrahamson, New York.—p. 817.

True Hermaphroditism: Report of Confirmed Case. R. C. Kell, R. A. Matthews and A. A. Bockman, Philadelphia.—p. 825.

Evidence of Communication between Renal and Omental Blood Vessels Following Nephro-Omentopexy for Arterial Hypertension in Man: Preliminary Note. M. Bruger and R. F. Carter, New York.—p. 832.

Pulmonary and Urinary Excretion of Paraldehyde in Dogs. J. H. Defendorf, Washington, D. C.—p. 834.

Observations on Etiology of Ulcerative Colitis: IV. Rectometrograms and Rectal Reactions of Eight Normal Subjects and One Patient with Ulcerative Colitis Before and After Spinal Anesthesia: Preliminary Report. R. Lium, Boston.—p. 841.

The Liver in Pellagra.—Since analogies have been drawn between pellagra and pernicious anemia, Sydenstricker and his co-workers tested the efficacy of an extract of pellagrous liver in the two diseases. The liver was secured from a patient who died of severe untreated pellagra, and an extract suitable for intravenous administration was prepared by the method of Cohn. This extract has been given to one patient with typical pernicious anemia and to two patients with endemic pellagra. The patient with pernicious anemia showed a prompt and satisfactory reticulocyte response with subsequent increase in erythrocytes and hemoglobin. The individuals with pellagra showed no evidence of improvement and were later brought into good remission by the intravenous administration of a commercial liver extract. This seems to indicate the entire autonomy of the factors effective in the cure of pernicious anemia and pellagra. The experiments suggest the existence of a factor other than nicotinic acid, active in the cure of pellagra, which is present in normal mammalian liver and its refined extracts but absent from the liver of pellagra.

Cardiovascular Syphilis.—Welty studied the clinical and pathologic records of 15,000 consecutive cases coming to necropsy at the Philadelphia General Hospital between Aug. 5, 1927, and June 15, 1937. Those presenting postmortem evi-

dence of cardiovascular syphilis were scrutinized in detail. Cardiovascular syphilis of all types was encountered in 1,040 (6.93 per cent) of the 15,000 cases. Males accounted for 74 per cent of the cases of cardiovascular syphilis, 76 per cent of aneurysms and 81 per cent of syphilitic aortic regurgitation. Negroes were responsible for the bulk of both the male and female groups. Though they formed only two fifths of the necropsies studied they accounted for 711 cases. Seventy-nine per cent of all patients were from 35 to 65 years of age; 76 per cent of cases of aortic regurgitation and 80 per cent of aneurysms were found in this particular age distribution. While crippling cardiovascular syphilis (aneurysm or aortic regurgitation) occurred in fifty instances in persons less than 35 years of age, in only four cases was one of these diseases encountered in a white subject. Comparing the two races, cardiovascular syphilis is much more prevalent in the Negro, attacks that race earlier in life and shows a tendency to develop a more serious cardiovascular lesion. Trends in the incidence of cardiovascular syphilis have been noted by only a few observers, and several of these reports have been contradictory. However, the majority of communications from the United States have shown some decrease in the frequency, both clinically and at necropsy. For purposes of contrasting the relative incidence in his own material, the author divided the 15,000 necropsies into consecutive groups of 3,000 cases each. Each group represents a period of from eighteen to thirty months, the variation depending on the increasing and changing number of necropsies from year to year. The first group coming in the years 1927-1930 showed a total incidence of 9.2 per cent; this subsequently dropped to 7.7 per cent in 1930-1932, to 6.36 per cent in 1932-1934, to 5.8 per cent in 1934-1935 and finally to 5.6 per cent in 1935-1937. In only 339 of the 1,040 instances was the syphilitic cardiovascular lesion the direct or an important contributing factor in the death of the patient. Thus in roughly two thirds of the cases it was a coincidental finding and, while it might have ultimately caused death, it actually had little to do with it. The mere anatomic demonstration of cardiovascular syphilis at the postmortem table does not mean that this lesion was the cause of death or even of the symptoms observed. Unless aortic regurgitation, aneurysm, coronary orificial stenosis or myocarditis, alone or together, are present there is no reason for circulatory insufficiency to ensue. As an explanation of the definite decrease in both the incidence of cardiovascular syphilis and its lessening importance as a cause of death the author offers modern methods of therapy.

Intermittent Venous Compression.—Kramer used intermittent venous compression in the treatment of 103 cases of impaired vascular circulation. The cases included diabetes, thrombo-angiitis obliterans, phlebitis, arteriosclerosis and four cases of painful ulcer. The best results were obtained in relieving fatigue; seventy-one of eighty-three patients with this complaint admitted improvement. The next best was its influence on cramps; fifty of sixty-five patients showed a decided improvement, and on pain, sixty-two of eighty-seven were relieved. There was a favorable influence on the symptoms in thrombo-angiitis obliterans; the percentages of the diabetic group were disappointing. The gratifying effects on fatigue and cramps presumably involve the tissue metabolites or other vasodilator substances and some beneficial effect on tissue metabolism. Collectively, this form of therapy gave an average of 78 per cent favorable influence on symptoms. The diabetic and Buerger's disease groups showed that 66% per cent were benefited. The arteriosclerotic group was disappointing, giving the lowest percentage (60) of those who were benefited. The phlebitis series showed a surprisingly high percentage, 72.8. The favorable results can be attributed to (1) the frequency of vasospasm associated with the phlebitis and (2) the combined therapy which was given to a majority of these patients. Some of them received mecholyl by iontophoresis, which has already been accredited as a successful form of treatment in phlebitis and varicose ulcers. Three of the ulcer patients showing some possibility of having a vascular disorder experienced relief.

Mass Immunization Against Diphtheria.—León and his associates report the data from investigations performed in Mexico by them on mass immunization against diphtheria with Sordelli's toxoid and the simultaneous immunization, active and passive, of the contacts with Sordelli's toxoid and antitoxin. They performed Schick tests on 4,309 persons of all ages. Readings were made from the first to the fourth day. They draw the following conclusions from their studies: 1. Sordelli's toxoid, acid precipitated and aluminum hydroxide activated, when injected in a single dose of 1.5 cc., having from 10 to 15 L_t (the volume of toxin flocculating with one unit of antitoxin) units per cubic centimeter, confers immunity to an average of 80 per cent of the susceptible persons. 2. The immunity induced with Sordelli's toxoid is acquired twenty days after the injection and remains at the same level for at least 307 days. 3. Higher proportions of successful immunizations are observed in the older age groups. This probably indicates that the doses of Sordelli's toxoid should be higher for the pre-school children than for school children and adults. 4. Mild and transitory local reactions were observed at the site of the injection in about 50 per cent of the persons injected and general reactions in 13 per cent. The use of Sordelli's toxoid is not contraindicated. 5. Sordelli's toxoid is a product that can be used with advantage in mass immunization against diphtheria since it immunized 80 per cent of the persons injected, but it would be convenient to prepare and use more potent toxoids, probably with not less than 30 L_t units per cubic centimeter, in order to obtain higher proportions of successful immunizations. 6. Simultaneous immunization, active and passive, against diphtheria can be induced with Sordelli's toxoid and diphtheria antitoxin if these products are injected subcutaneously, but at different sites, in doses in which the toxoid confers active and the antitoxin passive immunity when used separately. 7. Simultaneous active and passive immunization with Sordelli's toxoid

and antitoxin should be the method of election for the immunization of susceptible contacts with diphtheria cases or carriers, as with this method immediate protection is possible, which may last for a long time or permanently. Probably alum precipitated toxoid may be used as well as Sordelli's toxoid for this purpose.

Water-Borne Outbreak of Brucella Melitensis Infection.—An outbreak of eighty cases of infection with *Brucella melitensis* with one death, which occurred at Michigan State College, East Lansing, is discussed by Newitt and his colleagues. All the patients were students or others using a bacteriology building housing a laboratory that handled large numbers of brucella cultures. A faulty technic of sterilization of discarded cultures was demonstrated. Inadequate and faulty plumbing was found in which siphonage could be produced from the point at which contaminated glassware was washed. The onset of undulant fever is characteristically insidious and many of the patients were uncertain of the actual date on which illness began. There is evidence, however, that the incubation period varied widely. There were 210 students enrolled for laboratory courses in bacteriology who worked in the laboratories of the building. Frank clinical illness was present in thirty-seven cases, and twenty-eight were latent or subclinical. The attack rate varied with each of the eight bacteriology classes but of a total of 210 exposures the rate was 30.9 per cent. In addition to sixty-five cases in the regular classes, fifteen other cases occurred. Ten of these were of students in other courses who used the same laboratories for special assignments in parasitology and other subjects, one plumber, one stenographer, one stockroom attendant, one a student who paid social visits to a friend in one of the regular classes and one a salesman who made but one visit to the building. Therefore every person found to be infected with *Brucella melitensis* had been in the bacteriology building. Complete histories were obtained on all clinical cases. None of the patients had had any contact with goats or goat's milk. All evidence pointed to the faulty plumbing as a source of infection. The water supplied to the bacteriology building was obtained from the college distributing system through a 1½ inch service pipe. Immediately inside the building there is a T coupling diverting the water into two 1 inch lines, which extend around the building in opposite directions but do not reconnect. By opening several faucets in the basement a negative pressure was produced in the faucet at the sink at which the glassware from the brucella laboratory was washed. A negative pressure equivalent to 2 inches of mercury was recorded when all outlets in the basement were allowed to remain open. A new sink and two autoclaves were installed in the building during December (when the infection took place). The water main outside the building had been tapped for a service to a new building nearby. Thus, in addition to the possibility of negative pressure being created by the simultaneous opening of a number of outlets in the building, there were additional possibilities when the water was shut off during these installations.

Epidemic Encephalitis in California.—According to Wynn and Hawley, early in the summer of 1937 it was observed that the incidence of poliomyelitis and encephalitis in the San Joaquin Valley area of California was increased. While the number of cases was not great, many were severe and the mortality rate was high. It was assumed at first that there was an unusually high incidence of the encephalitic form of poliomyelitis, but as time went on it became evident that the disease was entirely distinct from poliomyelitis and that from the clinical standpoint it corresponded closely to the outbreak experienced in St. Louis in 1933. In all, 102 cases were recognized from March 1937 to February 1938. There were forty deaths. Blood was obtained from forty-one, usually during the stage of convalescence. Twenty-one of these neutralized the St. Louis type of virus. Geographically the disease was limited to the rural areas of the San Joaquin Valley section of California, while the metropolitan areas were relatively free. The incidence of the disease was definitely greater in the younger age groups than it was in the St. Louis outbreak of 1933. From three to six months after recovery, 22.5 per cent of the patients showed some disability which could be attributed directly to the disease. These ranged from headaches and weakness to spastic paralysis and mental changes. To Oct. 15, 1938, sixty-

six cases of epidemic encephalitis have come to the author's attention. Since writing their article the virus of equine encephalomyelitis, Western type, has been isolated in a fatal case from Fresno County. Therefore they consider it possible that some of the cases which have been negative for the St. Louis virus, as well as some of those who neutralized the virus, may have been due to the equine strain. With this in mind, serums are now being obtained from many of these persons for neutralization tests with the virus of equine encephalomyelitis.

Carcinoma of Uterine Cervix.—According to White, microscopic examination of adequate biopsy material is the only means by which cancer of the cervix can be diagnosed with any degree of precision, and little hazard is involved in properly excising biopsy specimens. Colposcopic examination and the Schiller iodine test are of academic interest. Both are greatly subsidiary to unaided visualization and biopsy. The Schiller test is a purely negative diagnostic method. Palpation of the cervical broad ligaments is satisfactorily accomplished by a combined vaginorectal examination. Cystoscopic appearances may be called into medicolegal evidence for the purpose of determining whether a subsequently developed fistula is the result of the disease or of the treatment. The rapidity with which a cancer spreads and metastasizes is a fairly constant index of the degree of malignancy of the primary tumor, but it is not an index of its curability at a given period. The majority of cervical cancers are radiosensitive; and the more active and anaplastic the cells, the less their radioresistance. Often nodes that are nearest the primary tumor, and which are naturally expected to be the first involved, are found cancer free, while a more distant group will show marked secondary deposits, a paradox in metastasis. There is a direct relationship between lymph stasis or lymphatic obstruction and the localization of secondary transplants. Cancer appearing in the cervical stump within one year after supravaginal hysterectomy is residual and was present before the operation. If it appears after a longer interval it must be considered a subsequent primary new growth. As prophylaxis against the latter event the mucosa of the cervical stump including the endocervix, if not destroyed by cautery at the time of operation, must be so destroyed within four weeks thereafter. Radium irradiation efficiently administered is the safest and most certainly curative method of treatment, but it must be supplemented by high voltage roentgen rays in all except the earliest cases. Primary roentgen therapy, supplemented by postradium roentgen irradiation, offers advantages that require further evaluation. Radium is by no means a simple remedy that may be applied casually without disastrous

effect or serious consequences. Therefore it should be used only by those who have had an opportunity through supervised experience to become expert in its application. Although the absolute curability rate for cancer of the cervix is between 20 and 30 per cent, half the total number of patients treated will die of the disease within three years.

Transurethral Prostatic Resection.—Thompson and Habin state that if transurethral prostatic resection has been done properly the functional results, both immediate and late, will be equal, if not superior, to those which can be obtained by any other type of prostatic operation. It is not unusual to admit a patient suffering from complete retention of urine, investigate his general condition and, if it is found satisfactory, perform the transurethral operation within forty-eight hours of his admission. Two or three days later drainage by urethral catheter is dispensed with and the patient usually is able to void a large stream painlessly and is able to empty the bladder completely. Within a week from the day of admission more than a fourth of the 1,200 patients of this series had been dismissed from the hospital. Thereafter they reported at the office daily until a fortnight or so after operation, at which time they were dismissed. Such a result is ideal and cannot be obtained when there are complicating factors such as severe uremia, cardiac decompensation, diabetes or advanced anemia, all of which require preoperative treatment. The urine clears progressively until, at the time of dismissal, it is only slightly hazy and sometimes is clear on gross inspection. Severe deformity of the bladder such as extreme sacculcation, diverticulation or deep cellule formation and renal deformity, such as hydronephrosis and hydro-ureter, complicate the case and delay the elimination of pus from the urine. The urine even in such cases became clear much more quickly than it ever did in similar cases following suprapubic prostatectomy. They do not administer urinary antiseptic in a routine manner with the single exception of methylene blue. This drug seems to have slight hemostatic properties and is an excellent postoperative medication. Incontinence occurs less often after transurethral resection than it does after suprapubic or perineal prostatectomy. Nocturia is relieved promptly; many patients have reported sleeping through the night without voiding, within two weeks after operation. The authors conclude that the results of transurethral resection at the hands of an experienced surgeon are superior to those obtained by either suprapubic or perineal prostatectomy.

Local and Regional Analgesia for Pain.—Steinbrocker points out that repeated injection with aqueous and oily solutions of 1 to 2 per cent procaine according to accepted anesthetic methods, at the site of pain or at the source of nerve supply to the painful area in a group of 134 patients with chronic, intractable discomfort, gave little or no relief in 20.9, slight improvement in 5.9, moderate relief in 13.4 and complete, lasting relief of pain in 59.7 per cent of the patients; that is, a total of 73.1 per cent of the patients experienced moderate or complete relief. A follow-up of nineteen patients for from four to thirty months after treatment showed that

seventeen were still adequately or completely relieved. Therefore the treatment of intractable arthralgia and allied painful states by local or regional analgesic injection offers a promising, palliative, accessory therapeutic measure in arthritis and related conditions.

Pneumonia Associated with Pregnancy.—Oppel analyzes the data in fifteen cases of pneumonia occurring during the period of gestation. Pneumonia is an infrequent but serious complication of pregnancy. Once it has developed, it is similar to pneumonia in nonpregnant women. It is difficult to establish that the mortality is appreciably altered by the presence of pregnancy. Patients may die or recover undelivered, but in the majority of instances they go into labor. Labor is apt to develop early in the disease but may begin late. It is frequently of short duration but may run the usual course. If the infant is of sufficient size and age, it will probably live. Common colds usually precede the development of pneumonia during pregnancy, and pneumonia is apt to develop during the puerperium in patients who have common colds at the time of labor. The adequate treatment of a common cold during pregnancy is an important way of preventing pneumonia during pregnancy and the puerperium. The management of the pregnant patient with pneumonia is essentially the same as that of any pneumonia patient. The data for determining the value of specific treatment of pneumonia of pregnancy are insufficient.

Fluids and Lumbar Puncture in Delirium Tremens.—Thomas and his colleagues compared twenty delirium tremens patients who had a lumbar puncture and were restricted in their intake of fluids and twenty who did not have a lumbar puncture and were given large quantities of fluids. All forty patients recovered from their delirium within one to three days after admission. However, the patients in the second group showed less tremor and fewer signs of exhaustion after the acute features of their mental disorder subsided than the patients who were restricted in their fluid intake and had lumbar puncture. Several patients of the latter group, who could not be kept in bed the usual length of time after the lumbar puncture, suffered from headache. The authors conclude from a careful scrutiny of the results of the two techniques that lumbar puncture is of great diagnostic significance in delirium tremens but that it is not an important factor in its treatment and that in the absence of intracranial complications (which are known to initiate an increase of cerebrospinal pressure) it seems wiser to give delirium tremens patients large quantities of fluids than to restrict this intake.

Maintaining Frontonasal Opening.—Williams and Fricke recommend the use of 1 mg. of radium, left in position for nine minutes, in the frontonasal opening postoperatively as a means of maintaining its patency. Closure of the frontonasal opening will inevitably result when symptoms recur. In forty-seven operations on the fronto-ethmoid group of sinuses, following which radium was not used, failure due to closure of the frontonasal opening resulted in 19 per cent. In sixteen operations on the fronto-ethmoid group of sinuses in which radium was used postoperatively there was a partial failure in the treatment of one patient because of partial closure of

the frontonasal opening by scar tissue, an end result which produces a percentage of failure of 6. Patients are too few for a percentage advantage to have much significance; however, the apparent success which radium has achieved lends encouragement to a continuance of its trial. The Lotherp technic was apparently of more value in preventing closure of the nasofrontal opening than was the use of radium. Not one patient whose frontonasal opening closed experienced symptoms of trouble sooner than four months postoperatively and, in every instance in which the frontonasal opening closed, recurrences took place within a year or less.

Reticulo-Endotheliosis.—Sweitzer and his associates present a case of reticulo-endotheliosis with cutaneous, osseous, splenic, hepatic and lymphatic involvement, but without the characteristic blood picture of the disease. There were two different types of lesions. In some areas tumors composed of reticulo-endothelial cells were found, and in other areas they were xanthomatous. The close resemblance of diseases involving the reticulo-endothelial system and the fact that they are not as sharply defined entities as has been thought previously are brought out by this case. There are cases, like this one, in which the borderline from one group to the other is crossed. The patient showed features of reticulo-endotheliosis as well as pathologic lipid storage in the scattered histiocytes of the reticulo-endothelial system.

Sulfanilamide for Lupus Erythematosus.—Wilson reports a typical case of acute disseminated lupus erythematosus in which well controlled sulfanilamide therapy produced no improvement. Because of the activity of sulfanilamide against the beta hemolytic streptococcus, found in cultures, the drug was used in the case reported. As efficiency results when a minimal level of 10 mg. of sulfanilamide per hundred cubic centimeters of blood is maintained, this concentration was exceeded throughout the course of treatment, twelve days. After this the patient became gradually weaker and died two days later. Postmortem examination revealed bilateral bronchopneumonia, pleural adhesions on the right side, abscesses of the left lung, hydropicardium, acute splenitis, cloudy swelling of the myocardium, liver and kidneys and chromaffin cell tumor of the right adrenal gland. There was no evidence of tuberculosis.

Pyogenic Dermatoses.—Strickler and Stone neither practice nor advise the use of sulfanilamide for the milder types of pyoderma, but as a result of their trial of sulfanilamide in two cases of impetigo of the neonatal period, six cases of secondary pyogenic dermatoses and four cases of sycosis vulgaris they are convinced that this remedy has a distinct field of usefulness in certain types of cases. These, they state, are pyodermas which may be fatal, those with a constitutional reaction which spread rapidly and chronic types (particularly follicular) for which the usual measures are without avail. All the authors' patients have been cured.

Changes in Angioscotomas from Sulfanilamide.—During the administration of sulfanilamide to two subjects Rosenthal observed that narrowing of the angioscotomas took place. From four to five days after the withdrawal of the drug, the angioscotomas had returned to normal. He believes that the changes observed were not due to oxygen deprivation, for, as shown by Evans and McFarland, angioscotomas widen under such conditions. Furthermore, there was no modification of the scotomas in one of the cases studied when oxygen was administered. The author offers two postulates: a relative increase in the oxygen present in the region of the retinal synapse and a possible specific influence of sulfanilamide directly or indirectly on the synapse and retinal nutritive state. It is possible that study of the angioscotomas during the administration of various agents may lead to a better understanding of the action of drugs on the human organism.

Sulfanilamide for Severe Corneal Ulcer.—Bailey and Saskin gave sulfanilamide to nine patients with severe corneal ulcers due to chemical burns or trauma. Long before the ulcers were healed the patients were relieved of their pain even while the ulcers were in a florid state. The authors are tempted, under the circumstances, to ascribe analgesic properties to the drug, for, with the delicate and exquisitely sensitive corneal fibrils still freely exposed, the patients declared that they were comfortable, that the ocular pain and headache were gone and that they were able to sleep throughout the night, whereas previously the pain was agonizing and sleep without an opiate was impossible. The fact that the chemical base of sulfanilamide is aminobenzene lends support to the suggestion that it has analgesic properties. When improvement set in it proceeded uninterrupted; the administration of sulfanilamide need not be persisted in until all objective signs of the lesions have disappeared. Rarely was it necessary to resume the administration of the drug. It appears that for ocular conditions the drug may be given with a greater margin of safety than for serious systemic infections in which the patients' vitality is greatly impaired. It is necessary to maintain a constant level of the drug in the blood; from 10 to 15 mg. per hundred cubic centimeters. When the drug is ingested at intervals of four hours, the ratio between absorption and elimination is such that this is achieved. All of the patients exhibited side effects, which, however, did not interfere appreciably with continuing the treatment.

Incidence of Trichinella Spiralis Infection.—In order to ascertain the prevalence of Trichinella spiralis in the New Orleans area Sawitz points out that a survey of its incidence in man, hogs, rats, mice, dogs and cats has been conducted.

He discusses the incidence in man, dogs and cats. Human diaphragms and pectoral muscles were obtained at unselected routine necropsies in the Charity Hospital and the Touro Infirmary. Diaphragms of dogs and cats were obtained from animals studied in various departments of Tulane University School of Medicine. Examination of 400 human diaphragms disclosed twenty-four cases of infection with Trichinella spiralis, an incidence of 6 per cent. Of the twenty-three cases in which both the diaphragm and the pectoral muscle were available, the diaphragm was found infected in twenty cases and the pectoral muscle in thirteen cases. Surveys in which diaphragms only are examined would thus miss 13 per cent of the cases. The diaphragm is qualitatively and quantitatively the better tissue for examination as the average number of larvae found in the diaphragm was 0.35 per gram as compared to 0.22 in the pectoral muscle. No history of clinical symptoms of trichinosis was found in any of the twenty-four cases. With increasing age the incidence of trichinella infection increased. The highest incidence was found in Negro women; the lowest in white women. The incidence of trichinella infections in 300 dogs was found to be 1.3 per cent, the incidence in ninety cats was 10 per cent. The incidence in cats is considered to serve as an indicator of the endemicity of trichinella infection in an area.

So-Called Biliary Cirrhosis.—Gibson and Robertson suggest that hepatic cirrhosis be defined as including parenchymal degeneration, fibrosis and nodular parenchymal regeneration. From a series of 244 cases of biliary obstruction and obstructive jaundice, there were twenty-one cases in which these conditions were associated with hepatic cirrhosis. In ten of these twenty-one cases the biliary obstruction was due to postoperative stricture of the common duct, in six to choledocholithiasis, in two to carcinoma of the ampulla of Vater and in three to other malignant lesions. An intermittent type of obstructive jaundice was present in fifteen of these twenty-one cases. The average case duration from the first onset of jaundice to death was three years. These factors may be involved in the production of regeneration in these cases. It is suggested that the term "biliary cirrhosis" be dropped and that for the infrequent combination of biliary obstruction, obstructive jaundice and true hepatic cirrhosis the designation "cirrhosis from biliary obstruction" be employed. Cases in which hepatic parenchymal damage without signs of regeneration follows obstruction of the bile ducts should be classified as instances of hepatic atrophy.

Pancreatic Necrosis and Pancreatitis.—Casberg reports five cases of acute interstitial pancreatitis and five of acute pancreatic necrosis. All the patients were treated conservatively; the first five recovered and the other five died. Investigation reveals differences which are significant if the condition called acute pancreatic necrosis is to be recognized; it is in cases of this condition that conservative therapy must be

replaced by laparotomy, if the exceedingly high mortality is to be reduced. Operation for drainage of the lesser peritoneal cavity allows active trypsin an exit and thus minimizes its destructive action on the pancreatic and surrounding tissues. Preparatory measures, such as transfusions and administration of fluids, must be used in view of the shock which is often present. The mortality from this disease will probably always be high, but a change from conservative to surgical therapy is indicated. A reasonable procedure would seem to be treatment by conservative measures during a preparatory period, followed by operation as soon as possible. Patients suffering from the transient type of interstitial pancreatitis recover promptly; the symptoms of those harboring a necrotic pancreas do not subside automatically. During the period of observation, patients with the latter entity can be appropriately prepared for an operative procedure and in this way the high mortality of laparotomy will be reduced.

Sulfapyridine for Pneumonia.—Hinshaw and Moersch discuss their experience with sulfapyridine in twenty-one cases of postoperative pneumonia and six cases of primary pneumonia. Patients usually were given 15 grains (1 Gm.) of sulfapyridine by mouth every four hours day and night. The maximal temperature of nearly half of the patients approached normal within twenty-four hours after treatment with sulfapyridine was begun. The condition of most of the others was significantly improved in from forty-eight to seventy-two hours. Postoperative pneumonia responded as well as primary pneumonia. Only one death occurred. This was in a case of early fulminating postoperative pneumonia which developed on the second day after extraperitoneal resection of a carcinoma of the colon. Some patients who did not respond to other treatment did subsequently respond to sulfapyridine. The diagnosis of pneumonia was confirmed by roentgen examination in every case. Sulfapyridine usually was withheld until there was evidence of serious progressive pneumonia. Most patients received nonspecific supportive treatment. Three patients received positive pressure therapy for pulmonary edema, with successful results. At least half of the patients in the series were so seriously ill that recovery would have been doubtful without sulfapyridine or specific therapy. More than half of the patients with postoperative pneumonia were 55 years of age or more. Only four patients were less than 45 years of age. Therefore the drug was equally effective in the treatment of both elderly and young patients.

Metabolism of Progesterone.—In investigating the metabolism and utilization of crystalline progesterone, Hamblen and his collaborators studied two groups of patients: one primarily in reference to endometriotropic responses and the other for the urinary excretion of sodium pregnandiol glucuronide. All of these had various degrees of alteration of ovarian function and all presented irregularities of menstruation as common symptoms. Endometriotropic responses were studied in twenty-three women during ninety-nine of 117 cycles of therapy with estrogens and/or progesterone. Some degree of progestational alteration was encountered at the end of twenty-two cycles, but only one normal progestational endometrium occurred, the remainder being mixed. Urinary tiers of sodium pregnandiol glucuronide were investigated during forty cycles of seven women, who received similar therapy during twenty-three of these cycles. No evidence was encountered in these studies that crystalline progesterone when given intramuscularly in oily solution is metabolized into sodium pregnandiol glucuronide. Apparently, when given alone, progesterone depresses the spontaneous metabolism of endogenous progestin. Endometriotropic studies suggest the possibility that the concurrent administration of estrogens with progesterone may enhance the utilization of the latter. The ineffective utilization of crystalline progesterone by the endometrium of these patients seems related to an inadequate metabolism of that sterol.

Desoxycorticosterone in Addison's Disease.—According to Thorn and his collaborators, intramuscular injections of a solution of synthetically prepared desoxycorticosterone acetate in oil (from 2 to 30 mg. daily) resulted in marked improve-

ment in the clinical condition of eight patients with Addison's disease during a period in which added sodium chloride therapy was withheld. The improvement consisted of increase in body weight, elevation of blood pressure, increase in plasma volume, restoration of plasma concentration of sodium, chloride and potassium to normal levels, positive sodium and chloride balance, increased renal excretion of potassium and inorganic phosphorus and improved muscular strength and sense of well-being. When desoxycorticosterone acetate was withdrawn for forty-eight to seventy-two hours there was noticeable weight loss, decrease in plasma volume, decrease in the total plasma content of sodium and chloride, a negative sodium and chloride balance, retention of potassium and inorganic phosphorus, muscular weakness, loss of appetite and the appearance of symptoms of adrenal insufficiency. Resumption of treatment again resulted in marked improvement.

Treatment of "Higher" Types of Pneumonia with Serum.—Dowling and his associates collected data in seventy-five cases which show that patients with pneumonia caused by pneumococci other than types I and II are benefited by the use of specific horse or rabbit serum. Hypersensitiveness to rabbit serum is not as frequent as is allergy to horse serum, whereas the percentage of serum sickness is about the same for the two groups. Results, as evidenced by a reduction in the mortality rate and decrease in the average length of hospital stay, were particularly good in cases of types V and VII pneumonia, as compared with cases not treated with specific serum. Treatment with serums of types III and VIII pneumonia shows some promise. Only a few cases caused by other types of pneumococci were treated. More work must be done before the value of serum in pneumonias caused by types III and VIII and the rarer types of pneumococci is certain.

"Benign" Lymphocytic Meningitis. J. E. Skogland, Minneapolis.—p. 462.

"Benign" Lymphocytic Meningitis.—Skogland reports the ten cases of lymphocytic meningitis that have been observed at the University of Minnesota Hospital within the last ten years. In one of these, antibodies against the virus of lymphocytic choriomeningitis were demonstrated in the blood serum. This case cannot be considered "benign," as it has run an active course for a year. In three of the other cases the neutralization tests were done on the serums five months, one year and two years respectively following recovery, with negative results. In the other cases the duration was brief (several days or a few weeks); complications were typically absent. The syndrome is characterized by symptoms of meningeal irritation and lymphocytosis in the spinal fluid. Because of the case in which antibodies against the virus of lymphocytic choriomeningitis were present in the blood, the author suggests that the term "lymphocytic meningitis" replace "benign lymphocytic meningitis," which is in common use.

Impetigo Contagiosa Treated with Ammoniated Mercury-Colloidal Kaolin.—Pratt and his associates found that an ammoniated mercury lotion containing colloidal kaolin to adsorb the vesicular exudate and form a firmly

adherent crust was more effective in curing impetigo in seventy-nine cases than was ammoniated mercury ointment alone in thirty-two controls. The time required for every crust to become detached and replaced by dry, smooth epithelium was two weeks or less in 62 per cent, while only 28 per cent of the controls were healed in that time. The average time for the test cases was fifteen days, while 26.9 days was required for the controls. There was no relation between the number of lesions and the time required to effect a cure.

Urticaria of Emotional Origin.—Blitz reports a case in which an itching rash suddenly appeared over the entire body. The patient had her first attack of urticaria three years previously, following the death of her uncle. There was no history of food or drug allergy, hay fever or hypersensitivity to cold. She attributed the present attack to an emotional upset. She saw her neighbor seized with a severe heart attack the day before. Calcium gluconate wafers, a saline cathartic and calamine lotion with 1 per cent phenol for pruritus were prescribed. At 10 o'clock in the evening of the same day the author was called to the patient's home because she suddenly fainted. On revival she complained of feeling weak and dizzy but declared that the itching had entirely ceased. On examination the skin appeared perfectly normal and there was no evidence of any of the urticarial wheals on the body. The patient attributed her fainting spell to an enema which was unexpectedly followed by her menses. After the pallor of the patient's skin disappeared, the pulse became fuller. The patient declared that she no longer felt weak or dizzy but again complained of intense itching over her entire body. After a lapse of about three minutes the urticarial wheals began to reappear over her entire body. The urticaria and pruritus gradually disappeared after eight hours. The author states that in syncope with the foregoing changes taking place, the interference with the blood supply to the skin may partly explain the mechanism of the interruption of wheal formation.

Oculoglandular Tularemia.—Oosting cites a case of oculoglandular tularemia contracted from the tree squirrel, probably unique in medical literature. The ocular lesions and the regional lymphadenopathy responded promptly and favorably to the antitularense serum therapy. The patient was given 30 cc. of Foshay antitularense serum in two doses of 15 cc. each, intravenously, on successive days. She had a cutaneous reaction to the antiserum consisting of a local erythema which Foshay considers to be a specific bacterial reaction rather than a manifestation of protein sensitivity. Following serum therapy, within three days the involved lymph nodes became greatly reduced in size, the conjunctival injection had almost disappeared and the conjunctival ulcers showed distinct evidences of healing. One week later the ulcers were completely healed, leaving no scars. On the fifth day after administration of the antiserum, serum sickness developed, but this responded to the usual supportive measures. The source of infection was undoubtedly the tree squirrel, as the patient had prepared squirrels for cooking eight and three days before inflammation of the eye occurred. It is probable that the infecting material was inadvertently carried to the eye by the fingers. This case emphasizes again the fact that the organism can penetrate the unbroken mucous membrane. The authors suggest that the diseases known to ophthalmologists as Parinaud's conjunctivitis and conjunctivitis infectiosa necroticans (Pascheff) bear close resemblance to oculoglandular tularemia. It seems quite probable that most or all of the cases described under these names were actually examples of oculoglandular tularemia.

Prontosil or Sulfapyridine for Rickettsial Diseases.—In guinea pigs infected with passage virus of Rocky Mountain spotted fever and endemic typhus and treated with soluble sulfanilamide, Topping noticed no benefit. In fact, he says that these guinea pigs did not do as well as the controls receiving infectious material and not treated. This was also true of guinea pigs infected with spotted fever and treated with sulfapyridine.

Diagnosis of Oxyuriasis.—Sawitz and her associates compared the efficacy of the zinc sulfate centrifugal-floatation technic, the brine centrifugal-floatation technic and Hall's cellophane-tipped glass rod (NIH swab) in the diagnosis of oxyuriasis. The detection of 14.2 per cent of the total positives (96.3 per cent) by the brine centrifugal-floatation technic, and 74 per cent by the zinc sulfate centrifugal-floatation technic, shows the definite superiority of the NIH swab technic as a means of detecting Enterobius infection. The studies were carried out on 136 institutionalized children in New Orleans. The incidence in the 109 boys and the twenty-seven girls was the same. Each repeated swab examinations, up to seven times, revealed additional infected children, making the 96.3 per cent. Further examinations on the remaining negative children remained negative, thus supporting the view that at least seven swab examinations are necessary before the absence of pinworm infestation is assured.

Sulfanilamide in Treatment of Brucellosis.—Condell reports five cases of brucellosis in the treatment of which he used sulfanilamide. He administered the drug for from twelve to eighteen days; improvement, which began from the third to the eighth day, continued and the patients have remained well. In addition to these five the author employed the drug in six other cases, which he feels were Brucella infections, but the diagnosis could not be confirmed by laboratory studies as it was in the five cases. All patients responded well to sulfanilamide and they have remained well. From this experience it is his opinion that sulfanilamide is a valuable drug in the treatment of brucellosis. In general there is usually an abrupt termination of fever and a relatively rapid recovery. This has been confirmed by other investigators.

Phagedenic Ulcer.—In the last year and a half Hirshfeld has treated successfully by zinc peroxide and excision two cases of chronic undermining nongangrenous burrowing ulcer and also a third case which he cannot classify definitely. In

the first two cases the ulcers harbored *Bacillus proteus*. This made all attempts to recover other organisms difficult and, the author thinks, may account for his failure to recover the organisms described by Meleney. In the third there was *Bacillus proteus*, but in spite of repeated attempts he was unable to isolate a micro-aerophilic nonhemolytic streptococcus or a micro-aerophilic hemolytic streptococcus. Zinc peroxide alone was powerless to control the lesions but, when used in conjunction with surgery, seemed to be of definite benefit. It was never able to stop undermining of skin, ribs or muscles, but, once these infected areas were completely removed, zinc peroxide appeared to prevent recurrence. The author has no proof of its mode of action and is unable to decide whether it acts specifically against anaerobic organisms by liberating oxygen, as Meleney believes, or whether it merely provides a comfortable nonadherent dressing which promotes drainage and requires such meticulous care of the wound that healing results.

Gallbladder and Biliary Ducts Operation.—Evans and Everts give an analysis of 645 consecutive operations on the biliary system. The cases are all from private practice, covering a period of seventeen years. In five cases the gallbladder had been previously removed, in five others it was not identified as such because of the extensive pathologic changes found in the common ducts, chronic disease of the gallbladder accounted for 467 of the cases and in 168 the condition was acute. Twenty-seven patients (4.1 per cent) died, death being due to myocardial disease, pneumonia, acute dilatation of the stomach, coronary disease and peritonitis. In general, the acutely diseased gallbladder cases in which it was possible to remove the gallbladder, surgery was resorted to earlier in the illness than in the "drainage cases." In other words, the more conservative the preoperative treatment the more severe was the pathologic condition found at operation. The remedy seems obvious; patients seen soon after the onset of symptoms should be operated on early. Since a large number of patients do not reach the surgeon until comparatively late in their illness, the greatest reduction in mortality will be dependent on the early surgical treatment of patients seen early in their illness. The plea for early operation is supported by the twelve deaths, ten occurred in cases in which it was impossible to remove the gallbladder because of the severity of the infection. All these patients had been given an opportunity to recover under conservative management, and surgery was resorted to only when it was seen that the disease was progressing. In the patients with common duct infections, much the same condition exists. Stricture of the common duct is a frequent cause of death following operations on the bile passages (14.2 per cent). Strictures that are due to injury of the ducts in the presence of severe inflammation can be eliminated in large measure by early operation. Strictures due to prolonged drainage by T tubes can be reduced in number by the use of straight tubes for a comparatively short period. The necessity for frequent drainage of the duct can be minimized by dilation of the sphincter of Oddi, permitting physiologic drainage into the duodenum.

Digitalis in Heart Failure with Normal Rhythm.—Gavey and Parkinson studied the clinical value of digitalis in sixty-five cases of heart failure with normal (sinus) rhythm and compared its effect in such failure with that in auricular fibrillation. After one week or more at rest in bed, digitalis leaf was given in a dose of 2 grains (0.13 Gm.) three times a day for from one to two weeks. The condition at the beginning of treatment with digitalis was compared with that at the end. The criteria of failure were dyspnea, enlargement of the liver and edema with or without hydrothorax. In the majority, 72 per cent, edema was present at the end of the week's rest in bed and in about 25 per cent hydrothorax was confirmed by x-ray examination. The control lay in the preliminary rest in bed without digitalis; but for comparison another series of thirty patients with failure and auricular fibrillation was observed in the same way. Under rest in bed only, in normal rhythm, seventeen of forty-seven patients improved; in auricular fibrillation eleven of twenty-eight improved. In normal rhythm some clinical improvement was demonstrated after digitalis in thirty-five of fifty-eight tests and twenty-three showed no improvement. Admittedly seventeen received only slight benefit, so that moderate or marked benefit resulted in only eighteen. There was little difference in response among the separate etiologic groups, though the response in the rheumatic group was best. The heart rate in failure with normal rhythm is moderate; the average before digitalis was given was 85. It was reduced by digitalis in twenty-seven of the fifty-eight tests (forty-seven patients). The average fall in rate was from 85 to 67. Whatever the initial rate, digitalis often reduced it. Reduction in rate was not always accompanied by clinical improvement, though improvement was rather more common in the patient who showed it. Diuresis was induced by digitalis in twenty-seven of fifty-eight tests (forty-seven patients) in normal rhythm. It was freer in patients with gross edema than in others. The course of the disease after the onset of failure in normal rhythm is short—eighteen of twenty-nine patients died within a year—and this in general must lessen the likelihood of improvement from digitalis. Yet in a particular patient the response to digitalis is no guide to the expectation of life; and if digitalis fails at a first trial, it may occasionally succeed at a later trial. Of the patients with auricular fibrillation, clinical improvement was demonstrated in twenty-three of thirty-two tests (thirty patients). The heart rate was higher than in the normal rhythm series, an average of 98 against 85. The rate was reduced by digitalis in the great majority by an average fall of 30. Most of those with slowing also showed benefit, but in the absence of slowing there was none. The rheumatic group was distinguished by a higher average rate before treatment, by reduction of the rate in all fourteen cases, and by clinical improvement in all but two. Without the rheumatic group, the fibrillation series responded to digitalis no better than the normal rhythm series. A mercurial diuretic sometimes administered after a digitalis test nearly always produced a free diuresis even when digitalis had failed. In edematous patients other than those with rheumatic auricular fibrillation and a high ventricular rate, a mercurial diuretic usually had more value than digitalis. Yet a trial of digitalis cannot be omitted, for it alone acts directly on the heart. The partnership of a mercurial diuretic with digitalis should govern the treatment of heart failure. Digitalis is always indicated in con-

gestive heart failure irrespective of rhythm, but it is often inefficient, as it fails completely in about a third of all cases. The real difference in the response of heart failure to digitalis lies not between auricular fibrillation and normal rhythm but rather between rheumatic auricular fibrillation and all other kinds of heart failure irrespective of rhythm.

New Sign of Left Ventricular Failure.—A widened P wave of low voltage, usually bifid or flat topped, has been found by Wood and Selzer in association with left ventricular failure in cases of hypertensive heart disease and aortic incompetence. It is suggested that this P wave results from left auricular stress.

Transplantation of Gracilis Muscle for Incontinence.—Loughnane points out that the multiplicity of operations devised to cure urinary incontinence is striking testimony to their ineffectiveness. Most of them function by producing a stricture or narrowing of the urethra. Deming was the first to utilize the gracilis muscle, in a case of epispadias and exstrophy of the bladder, using the whole muscle. The author transplants only part of the muscle to produce a sphincter in women to cure incontinence, with satisfactory results. He cites eight cases in which complete or almost complete control has been obtained.

 *Adult Serum in School Epidemic of Measles. L. R. Lempriere.—p. 1136.

After-Results of Child Guidance.—A follow-up inquiry was carried out by Maberly and Sturge on a group of 1,330 children attending the Tavistock Clinic for treatment between 1921 and 1934; 500 replies were obtained and analyzed. Of those who did not reply, 150 were visited to determine the reason; the present condition of these patients was entirely comparable to that of those who did reply. Of those who did reply, a group of 160 cases were visited to verify the reliability of the written replies. No significant difference was found. Treatment varied in type, ranging from simple advice to parents in a few interviews to lengthy treatment programs involving, besides psychiatric interviews, play therapy, coaching, social work and foster-home placement: sometimes all these were applied to one child. The inquiry showed that three or more years after treatment was stopped improvement in the condition for which treatment was sought is still present in more than 77 per cent of the children. If all the children who received further treatment are excluded, the figure is 70 per cent. Little or no significant variation in the degree of improvement could be found between the two sexes, in different complaints or in sibling relation in the family. Children with an average intelligence responded better than those with higher or lower than average intelligence. Of 121 patients who had passed through adolescence, the proportion relieved was the same as that for the whole group.

Adult Serum in a School Epidemic of Measles.—Lempriere discusses the value of adult serum in a school epidemic of measles. The first two cases of measles at the school, as far as could be ascertained, were independent of each other. The latter case, which occurred in the sixth form, did not lead to subsequent cases. There were in all 530 boys in the school, of whom 139 were presumed to be susceptible to measles in

view of their negative history as regards a previous attack. Measles developed in 120 of these 139 boys. In addition, measles developed in five boys with histories of having had a previous attack and who therefore did not receive serum. Among the 139 presumed nonimmune boys, twenty-three received no serum for one reason or another and together with the five who had received 20 cc. of adult serum, while to one boy 5 cc. of convalescent serum was given at his private doctor's request. The serum was administered to the first series of contacts between the fifth and the seventh day after earliest known exposure. As the epidemic was observed to spread with no readily defined limits, the remainder of the presumed nonimmune boys were inoculated, irrespective of whether contact was known or not. Although the complications, including encephalitis, were mild and never constituted a threat to life, their greater frequency (17.9 per cent) among the controls suggests that the serum was probably responsible for the more favorable results (4.16 per cent) in the inoculated group. The degree of illness among the controls was severe in eighteen, average in six and mild in four as compared to average in twenty-five, mild in thirty-six and extremely mild in thirty-five. The epidemic was a comparatively mild one, although some of the boys had quite sharp attacks. Although as many as 101 patients were under treatment at a time, the epidemic lasted as long as seven weeks. By the end of that time all but 13.7 per cent of the presumed nonimmune boys had suffered an attack. In spite of the rather poor results on paper, the author is convinced that, after making full allowance for the influence of all factors, adult serum, even in the small doses used, exerted a beneficial effect, as shown by a less severe illness and a diminished incidence of complications in the majority of the inoculated boys, compared with those boys who were not given serum. This epidemic was freer from complications and anxieties than any of its predecessors, a view shared by the nursing staff and by all house officers.

Testosterone Propionate in Enlarged Prostate.—Sharpey-Schafer and Shackman studied the microscopic appearances of an enlarged human prostate before and after the injection of large doses of testosterone propionate. No striking change was produced in the appearance of the enlarged prostate after the injection of the testosterone propionate. So far as is known to the authors, the dosage (3,400 mg. over a period of thirty-four days) was greater than has been given by most other workers. It has been suggested by Champy and Coujard that the effect of androgens in relieving symptoms of prostatic obstruction may be due to an action on plain muscle. In the case reported, suprapubic drainage precluded any observations on such a possible action. The apparent decrease in the size of the gland was not regarded as necessarily due to the testosterone propionate, as an enlarged prostate may apparently decrease in size either spontaneously or after suprapubic drainage of the bladder.

Prognosis in Acute Nephritis in Childhood.—Tallerman and Burkinshaw give the results of a follow-up study of twenty-five patients with acute nephritis carried out after a minimal period of eight years had elapsed from the time of the original

attack. Only sixteen of these patients came for the follow-up reexamination, seven could not be traced and two were unable to come because of their work but were apparently in perfectly good health. Five of the patients reexamined had completely recovered, eight have recovered although a trace of albumin was found in their urine, one has probably completely recovered and two have some renal damage. Of the eight patients with a trace of albumin in the urine, four are girls more than 12 years of age and the source of the albumin may well have been vaginal rather than renal. In delivering a prognosis, critical consideration must always be given both to any impairment of renal function and to albuminuria, although really slight deviations from normal in the former may not be of any significance and albuminuria may be orthostatic and does not seem necessarily by itself to be a matter of serious prognostic importance.

Obstruction in Fatal Pulmonary Embolism.—From the records of 130 cases of pulmonary embolism found among 2,861 postmortem examinations, Pilcher draws the following conclusions: 1. When a pulmonary embolus is the cause of death it is large enough to cause serious obstruction of the pulmonary circulation. 2. In more than half the cases the embolus occupied the trunk of the artery or both main branches. 3. When death follows a small embolism it can rarely be attributed to the embolism alone. 4. In healthy subjects death from pulmonary embolism is sudden in a minority of cases. There is no basis for the belief that injecting sympatheticomimetic or antispasmodic drugs does anything except postpone death for a short time. However, the results of embolectomy should be more encouraging. If the diagnosis of an obstructive embolus can be made with confidence, embolectomy should be undertaken; even if at the onset obstruction is incomplete it is likely to become complete as the result of secondary clotting unless the embolus is rapidly dislodged or fragmented.

*Study of Urinary Estrogen in Four Cases of Dermatologic Disorders. M. Sorba.—p. 483.

Urinary Estrogen in Dermatologic Disorders.—Since an endocrine factor supposedly is a factor in certain dermatoses, such as juvenile acne, Sorba decided to study the urinary estrogen in cases of this type. He discusses the determination of estrogenic substances in the urine and then reports the clinical histories of three women and a child aged 5, in whom he investigated the estrogen in the urine. He found that in the child with gonococcal vulvovaginitis the content of estrogen was always less than 10 mouse units per liter. In a case of colliquative flord acne coexisting with menstrual disturbances, he detected a maximum elimination eleven, twelve and thirteen days before the onset of menstruation, which corresponds to the classic hyperestrogenuria of the period of ovulation. In a case of sarcoïd of Boeck, in a woman whose menstruation and genital tract were obviously normal, the urinary estrogen was studied for five consecutive months; that is, during five complete menstrual cycles. The first cycle presented three maxima. The others could be reduced to a type with a single maximum, although they differed considerably in detail. In a case of polymorph juvenile acne without menstrual disturbances the author observed in two consecutive cycles a maximum which began from thirteen to eleven days before menstruation. The curves gave the classic appearances. It was observed also that the injection of large doses of estrogenic substance (10,000 units) fails to provoke a modification of the amount in the urine. The author stresses among other factors that in the same woman with normal menstruation the curves of urinary estrogen can be of different types in different cycles. The extreme diversity of results may perhaps be explained by the fact that it is possible to determine the quantity of estrogenic substance that is excreted but not the amount utilized by the organism. In the cases described in this report, no new type of curve was observed and they are not sufficiently numerous to permit the establishment of a relationship between the estrogen in the urine and the investigated dermatoses. In the first case of acne, estrogenic substance was always eliminated in detectable quantities except during six days. A single determination during these six days had led to the diagnosis of hypo-estrogenuria, which the rest of the curve demonstrated to be incorrect. The case of Boeck's sarcoïd provided an analogous example. This proves the value of continuous curves. The two cases of acne showed curves of urinary estrogen with a single maximum, approximately near the middle of the cycle. They do not present hypo-estrogenuria. The menstrual disturbances presented by the first woman were absent in the second one. In spite of this difference the appearance of the curve was identical in the two cases. It will be desirable, especially in cases of acne, to repeat these tests together with the determination of the hypophyseal gonadotropic hormones. This may perhaps elucidate the mechanism by which the hypophysis and gonads intervene in acne.

*Immediate Treatment of Postoperative Phlebitis in Gynecologic Surgery by Infiltration of Lumbar Sympathetic. R. Démarez.—p. 364.

Infiltration of Lumbar Sympathetic in Postoperative Phlebitis.—According to Démarez the treatment of phlebitis until recently has consisted in complete immobilization, which is prolonged until all fear of fragmentation of the clot has been completely removed. The estimation of the duration of this immobilization is difficult, but six weeks is usually required.

Such prolonged immobilization favors the appearance of grave sequels such as muscular atrophies, articular ankyloses and osseous disturbances. The author shows that great changes have been brought about in the therapy of phlebitis by giving attention to the vasomotor or sympathetic manifestations which accompany the obliteration of the vein. Among the signs which characterize the neurosympathetic syndrome of phlebitis he mentions (1) irradiation of painful areas elicitable at the plantar point, on pressure of the achilles tendon, at the base of the trigonum femorale and so on; (2) involvement of the vasomotor regulation, which becomes manifest by the appearance of bluish areas on the limb and by a considerable augmentation of the local temperature; (3) disturbances in the sudoriparous and the pilomotor reflexes. Moreover, the fact that Aldrich's test is greatly accelerated at the onset of phlebitis, even before edema is clinically perceptible, is regarded by the author as an additional sign of the neurosympathetic syndrome, for he has been able to show that anesthetic infiltrations of the lumbar sympathetic produce an acceleration of the resorption time of the wheal. The author says that Leriche arrived at the following conception of the physiopathology of phlebitis: The phlebotic edema is not due simply to stasis but the alterations in the venous walls (inflammation or localized thrombosis) irritate the perivenous sympathetic ramifications, which elicit, by way of reflex action, vasomotor phenomena which result in an arteriolocapillary vasoconstriction. This conception of the role of the sympathetic in the physiopathology of phlebitis leads to therapeutic deductions. The majority of the vasomotor reflexes produced by phlebitis of the inferior member pass through the ganglions of the lumbar sympathetic chain. Accordingly, the anesthetic blockage effected at this level suppresses the spasmodic accidents. Infiltration of the lumbar sympathetic deserves a trial at the onset of postoperative phlebitis. The author, after pointing out that Leriche and Kunlinun reported their first experiences with this method in 1934, describes his own observations in three cases. Discussing these cases, he stresses that the infiltration must be made at the onset of the disorder, when the reflex and spasmodic phenomena predominate over the mechanical consequences of obliteration. If Leriche's method is employed early, it produces excellent results. The pain disappears, the temperature decreases, edema either does not appear or it never attains the importance which it has when the phlebitis is treated with the old method. Moreover, the member does not have to be immobilized; the patient can get up and walk after from twenty to twenty-four days, which is considerably less than the six weeks required by the procedure of complete immobilization.

*Physicochemical Syndrome of Duhring-Brocq's Disease (Dermatitis Herpetiformis). R. Turpin, P. Chassagne and R. Cavier.—p. 933.

Investigations on Occult Deficiency of Ascorbic Acid. A. Iancou, C. Opris and V. Julia.—p. 936.

Habitual Onset of Pulmonary Tuberculosis in Adults. C. L'Adulte.—p. 937.

Physicochemical Syndrome of Dermatitis Herpetiformis.—Turpin and his associates made physicochemical studies on patients with dermatitis herpetiformis (Duhring-Brocq's disease). They report studies on the hemal and phlyctenar proteins, on lipemia and cholesteremia, on the distribution of sodium chloride, and on calcium, magnesium, sodium, potassium and the alkali reserve. They found that the disturbances in the hemal proteins are profound and permanent. The hypo-proteinemia is due chiefly to the diminution of the albumin content of the serum. The albumin/globulin quotient is reduced. The euglobulin of the serum is not modified. The fluid of the phlyctenae is rich in proteins. The globulin content is superior to the albumin content. Once the authors found an albumin/globulin quotient of 0.32 and another time of 0.63. The determination of the lipids of the blood revealed normal figures, and cholesteremia was likewise normal. The lipo-albuminous index was normal. The study of the effects of dechloridation and rechloridation revealed that the distribution of the chlorides and their elimination are normal. The plasmatic and urinary chlorine values do not deviate from the physiologic limits. The chlorine of the phlyctenar fluid reflects the variations of the plasmatic

chlorine; but the authors observed that the ingestion of large doses of sodium chloride favors the phlyctenar crops. The mineral equilibrium of the blood is impaired. The calcium content is reduced by diminution of the proteinic calcium. The ionized calcium is normal; calciuria is not modified. On the other hand, kaliemia is increased and the hemal potassium calcium ratio reaches 4.1 (normal 1.8). This hyperpotassemia, jointly perhaps with the muscular disintegration and the cachexia, is accompanied by hyperpotassuria with diminution in the urinary sodium/potassium ratio. The hemal and urinary magnesium and sodium values deviate from the normal. The determination in the serum of the polypeptides, of urea and of the alkali reserve give normal values. The urines contain only indeterminate traces of albumin. In the course of postmortem examination the authors observed deep hepatic changes: hepatomegaly with lesions of fatty degeneration especially in the periportal region. Their results do not permit a capacity of substitution of hypoproteinemia to be attributed to the hemal lipids. They state that the observed plasmatic disturbances favor the development of an edema, which however does not accumulate in the interstitial spaces because it is drained by the cutaneous ulcerations. In the long run cachexia develops, favored by the dehydration and the secondary infection; the muscular fusion is doubtless responsible for the hyperpotassemia and the hyperpotassuria. The authors think that it seems justified to group dermatitis herpetiformis with disorders that are allied to hyperallergy, such as Quincke's disease, asthma, migraine and eczema. This pathogenic conception is most in accord with the facts; the relapsing phlyctenular crops involve considerable proteinic spoliation; the organism compensates the losses less well because the liver is greatly altered and not equal to its task; the albumin is replaced less quickly than the globulin, and proteinic disequilibrium is added to hypoproteinemia. The diminution of the calcemia is the result of a decrease in the proteinic calcium and does not involve the ionized, physiologically active fraction; thus the hypocalcemia leads neither to a neuromuscular excitability nor to calciuria. The authors conclude that these different metabolic disturbances deserve to be classed with the symptoms of Dühring-Brocq's disease; they represent a physico-chemical syndrome complementary to the clinical signs.

*New Methods in Combating Tetanus. G. Ramon.—p. 981.

Microfilarial Arthritis of African Onchocerciasis. L. Déjou.—p. 983.

Tetanus.—According to Ramon, the efficacy of preventive serum therapy, however valuable as a prophylactic against tetanus in patients without previous serum inoculation, has a restricted application because, as is well known, the immunity conferred is of short duration and the antitoxin administered is rapidly eliminated from the human system. This rapid elimination may be the cause of the retarded appearances of tetanus noted in the World War. Combination of anatoxin treatment with preventive serum treatment consists in giving the patient a first subcutaneous injection of anatoxin with a potency of 1 cc. some moments before the administration of the preventive serum (minimum dosage of the latter is 3,000 units) followed two weeks later by a second injection of 2 cc. of anatoxin and two weeks after this by a third injection of 2 cc. and by similar injections in the event of subsequent recurrences of traumatism. According to the specific anatoxin therapy of tetanus in evolution, a single heavy dose of tetanus antitoxin (150,000 units or eight ampules of 10 cc. each of 20,000 unit strength) and 2 cc. of anatoxin is given after diagnosis and progressively increasing doses of 2, 4 and 6 cc. of anatoxin within five or six days. Subsequent injections, as necessary, may be performed without fear of negative reactions. Experiments and clinical observations prove the efficacy of this method. Its advantages consist in reducing the quantity of serum otherwise required to prolong immunity and in thus diminishing the evil effects that might result from too intense a serum therapy. Likewise, in assuring the permanence of immunity it protects the patient against the risk of a subsequent activation of a tetanigenic focus. In discussing the third method, that of "solutions with tetanus antitoxin," the author indicates its prophylactic properties against serum accidents. These solutions contain from ten to twenty times less protein than raw horse serum. By diluting

0.5 cc. of an antitetanus serum, either purified or unpurified, of 7,000 unit strength with 9.5 cc. of physiologic solution of sodium chloride an antitoxin of 3,500 units (the dosage required to prevent tetanus in an uninoculated person) is obtained, containing twenty times fewer proteins than the 10 cc. of antitetanus serum ordinarily employed in similar cases. A small amount of formol is added and heated for an hour at 55 C. This solution, the author says, has been found useful in diminishing the frequency and intensity of "serum accidents." General estimates place these at 40 per cent in adults subjected to antitetanus serum therapy. The rate for its incidence in the army mounts to as high as from 50 to 70 per cent with ordinary serum and from 10 to 25 per cent in so-called purified serum. The reports of the use of this "solution of tetanus antitoxin" are highly favorable. In 150 cases unfavorable consequences were few; in 100 others there was only a single appearance of general urticaria of short duration. Of thirty-one army patients only one showed a light local reaction, which soon disappeared. He had been treated with preventive serum during the war. The author devotes a section to the discussion of the procedure of obtaining antitetanus serum of a high antitoxin content by hyperimmunization of horses. The output of available units of antitoxin is thereby enormously increased. He also points out other benefits of a serum of high antitoxic potency, such as the appreciable reduction of serum injections and its invaluable aid in preventing tetanus in injured persons without previous inoculation.

Observations on and Treatment of Voice After Surgico-otogenicologic Therapy of Cancer of Larynx. R. Luchsinger.—p. 561.

Central Azotemias.—Mach and Naville say that the cerebral lesions caused by intoxication with carbon monoxide have been known for a long time but that little is known about the effects of poisoning with illuminating gas on the metabolism of proteins. They had the opportunity to observe a case of poisoning with illuminating gas in the course of which there developed an extremely high azotemia. After describing the clinical history of this case they discuss (1) the lesions of the nervous system which develop in intoxication with illuminating gas and (2) the pathogenesis of the azotemias secondary to these lesions and the problem of azotemias of cerebral origin which are designated as central azotemias. Summarizing their observations, they say that following intoxication with illuminating gas the woman presented lesions of the central nervous system and a severe azotemia, without edema or hypertension. The azotemia of this patient is secondary to the cerebral lesions that are caused by the intoxication. The azotemias which are observed in the course of disorders of the nervous system are not, as a rule, accompanied by a nephritis but by disturbances in the renal function as well as by intense proteinic disintegration. Exceptionally there may develop, following a nervous lesion, a true nephritis which is cured when the primary cause, the nervous disturbance, disappears. In the presence of a nervous disorder in a patient with azotemia, it should not be always affirmed that the lesion of the brain is necessarily secondary to that of the kidneys but it should be taken into account that there is a possibility of an azotemia of central origin with or without nephritis.

Adeno-Epithelioma of Sweat Glands Developing Into Melanoblastoma. N. Maggi.—p. 150.

*Syphilis of Cardiovascular System. M. Venzoni.—p. 171.

Aneurysms, Crysts and Secondary Tumors of Thoracic Duct. M. Sindoni.—p. 211.

Syphilis of Cardiovascular System.—Venzoni reports the results of work done for the last ten years in the dissecting room of the Institute of Anatomy and Pathology of the Hospital of Venice on syphilis of the cardiovascular system. In a

total number of 9,807 necropsies which the author carried out he found that syphilitic aortitis was present in 199 cases. Of these, 164 were cadavers of men and thirty-five of women. The age of the patients at death was between 35 and 80. The syphilitic lesion involved the thoracic and lumbar segments of the aorta in 104 cases and the arch in sixty-four cases. Arteriosclerosis coexisted in eighty cases. In fifty-seven cases there was aneurysm, which was located at the arch in thirty-six cases. Aortic insufficiency existed in fifty-seven cases (as shown by the results of the hydraulic test and by the degree of hypertrophy of the heart). There was coronary stenosis (of one or both coronary arteries) in 105 cases, coronary sclerosis (with calcification and diminution of the lumen of the vessels) in thirty cases, productive sigmoiditis in thirty-one cases and nonrheumatic endarteritis in twelve cases. Sudden death had taken place in thirty-nine, in which it was found that stenosis of the coronary arteries (sixteen cases), aortic insufficiency (four) or coronary stenosis in association with valvular insufficiency (eleven) existed. The microscopic picture of vascular syphilis depends on the extension of the lesion. In the aorta and large vessels the histologic aspects show predominance of mesarteritis, inflammation, acute hyperplasia, infiltration, dissociation and destruction of the walls and infiltration and hyperplasia of the intima. In vessels which do not directly bifurcate from the aorta, mesarteritis diminishes and periarteritis and endarteritis persist. Endarteritis is marked at the points of bifurcation of the coronary and carotid arteries. Arteriosclerosis is frequently associated with cardiovascular syphilis but it has no role in the selective location of syphilis. However, cardiovascular syphilis favors the local development of arteriosclerosis.

*Roentgen Treatment of Pulmonary Metastases of Sarcoma. A. Gregori. —p. 439.

Roentgen Treatment of Pulmonary Metastases of Sarcoma.—According to Gregori, sarcoma and sarcomatous metastases of the internal organs (those of the lung being included) can be controlled up to production of clinical recovery of the patients by administering large doses of x-rays. Almost all forms of sarcoma, including hypernephroma, may produce metastases to the lung. During the last ten years the author gave the treatment to thirty patients who were suffering from pulmonary metastases from sarcoma. The nature of the primary tumor was verified in all cases by microscopic study either of the tumor which was removed during a surgical operation or of tumoral tissues that were taken for biopsy. In the majority of the cases the treatment controlled the metastases. The span of life after the roentgen treatment varied between six months (fourteen cases) and four years (ten cases). In six cases complete disappearance of the pulmonary metastases and clinical recovery was obtained. The four patients who had solitary large metastases of the lung are living and in good health within five and ten years after administration of the treatment. One of the two patients who had bilateral multiple metastases is living up to the present (five years after the treatment) in good health. The other one died five years after treatment. The technic followed by the author is intermediate between Pfahler's roentgen saturation and Coutard's fractional irradiations, which are administered over a long period. In the treatment of sarcomatous pulmonary metastases one cannot give fixed standards, as it varies with the seat and size of the metastases. The irradiations have to be given only over the tumor in such a manner as having the irradiating beam acting as a bistoury on the tumor without striking normal tissues around it. When the metastases are alone, the irradiations are given through three ports of entry, at the dose of 250 roentgens for each treatment. Only one field is irradiated at a time. A normal cycle of treatments lasts between four and six weeks. In a few cases administration of a second cycle is indicated. As a rule the pulmonary metastases entirely disappear after one or two cycles of treatment and the patients obtain a lasting clinical recovery, which is shown by the general improvement of the patient, the prolongation of life and the absence of x-ray signs of the preexisting metastases in the lung.

Problem of Pancreatitis. A. Rodriguez-Ollerios.—p. 297.

*Treatment of Pyothorax in Course of Artificial Pneumothorax. J. Garcia Bengochea.—p. 331.

Treatment of Pyothorax.—Garcia-Bengochea reports the results of various treatments which he carried on in twenty cases of pyothorax in the course of artificial pneumothorax. There were sixteen cases of pleuropulmonary perforation. Early pleurotomy with the smallest incision was done in seventeen cases (which included the sixteen cases in which pleuropulmonary perforation existed). In the group of four cases in which pleuropulmonary perforation did not exist, treatment consisted in partial thoracoplasty, pleural lavages in association with pleural aspiration, punctures for evacuation of the fluid and, in one case, late pleurotomy. Thoracoplasty was done in nine cases in the whole group, with six recoveries. Seven patients in the whole group died from rapid bilateralization of pulmonary tuberculosis, notwithstanding the fact that early drainage was resorted to. Two patients improved and the condition of two patients did not change. The author concludes that the results of any of the various methods which are used in the treatment of pyothorax in the course of artificial pneumothorax largely depend on the selection of the method in relation to the clinical form of the disease. Lavages of the pleurae give more satisfactory results than pleurotomy with the smallest incision, when they are done early at the development of the disease, by the proper technic and only in cases in which pleuropulmonary perforation has not occurred and pachypleuritis and peripleuritis have not developed. Pleurotomy is indicated in nonsepticemic forms of pulmonary tuberculosis in evolution and, as an operation of emergency, in pleuropulmonary perforation and in hypertoxic pleurisy. Pleural aspiration is of value in malignant pyothorax, provided pleuropulmonary perforation or tuberculous pulmonary lesions in evolution do not exist. When the operation is done according to proper indications, the suppurating surface of the pleura is reduced and the lung is reexpanded. If the operation does not suffice by itself, the extension of the following thoracoplasty is reduced. The best treatment of pyothorax as a complication of artificial pneumothorax is to prevent it by immediate and permanent discontinuation of insufflations in all cases in which pneumothorax is insufficient during the first three months of its establishment.

Action Mechanism of Gonadotropic Hormones of Anterior Lobe of Hypophysis and of Follicular Hormone. H. Winkler and A. Binder.—p. 877.

Insufficiencies of Anterior Hypophysis Following Hemorrhages.—Effkemann and Müller-Jäger point out that it has been reported that ischemic necroses of the anterior lobe of the hypophysis develop frequently after severe partum and postpartum hemorrhages. They also mention observations by Erdheim and Stumme on the gravidic hyperplasia of the hypophysis and then cite numerous clinical pictures indicating a hypophysial disorder which are observed following childbirth. Since in the literature it is stated repeatedly that such disorders are the result of severe postpartum hemorrhages, the authors decided to make follow-up examinations on women in whom childbirth had been complicated by severe hemorrhages. They were able to reexamine eighty-six women who had given birth during the years 1928 to 1935. They found that genital atrophy with hypomenorrhea, sterility and adiposity were comparatively frequent in these women in later life. It is probable that these manifestations are connected with the postpartum hemorrhages. Moreover, hypogalactia, emaciation and menstrual anomalies also showed a more than normal frequency in this material. The authors show that there are many factors which indicate that these symptoms are not caused by the postpartum hemor-

rhages but that these hemorrhages or atony are more frequent in the women with the endocrine predisposition for the aforementioned symptoms. They also reject the theory that the postpartum hemorrhages contribute to the pathogenesis of endocrine disturbances that are due to impairments in the hypophyseal-diencephalic system. They think that women with a latent predisposition to such endocrine disorders are also predisposed to postpartum hemorrhages.

Action of Fresh and Hemolyzed Blood on Erythropoiesis.—Schernhardt cites reports from the literature which indicate that in hemorrhagic anemias with internal bleeding recovery is much more rapid than in those with external bleeding; that is, if the products of disintegration of the erythrocytes remain in the organism, recovery is more rapid than if this is not the case. He further mentions investigators who injected hemolyzed blood into anemic patients and says that many authors obtained favorable results by artificial hemolysis. In all these cases the erythropoietic action was the result of a disintegration of erythrocytes within the organism. Moreover, roentgen rays if applied in small doses exert an erythropoietic effect, but if applied in large doses they have an erythropenic action. In case of the small doses the destruction of erythrocytes on a small scale has a stimulating effect on the erythropoiesis. In his own studies the author investigated the behavior of the erythrocytes, on the one hand, in case of intramuscular injection of the person's own blood and, on the other hand, in case of the intravenous administration of hemolyzed blood. He aimed to determine to what extent the reaction elicited by the fresh as well as by the hemolyzed blood was dependent on the quantity of blood. In case of autohemotherapy he experimented with injections of 2 cc. and of 20 cc. daily for a period of ten days. In the cases in which 2 cc. was given daily he observed erythropoiesis; in the cases in which he administered 20 cc. he observed erythropenia. The intravenous injections of hemolyzed blood he made with 2 cc. and 15 cc., respectively, for three days. He observed that in case of the administration of the large doses the number of erythrocytes decreased by from 600,000 to 800,000, whereas in case of the small doses they increased by about the same amount. The author emphasizes that neither in case of the fresh nor in case of the hemolyzed blood is the effect due to substitution but rather to stimulation of the erythropoiesis.

Roentgenologic Observations in Cardiac Pulmonary Stasis.—Gross and Müller demonstrate that the roentgenogram permits an estimation of the functional capacity of the heart. The outline of the heart gives information about the nature of

the existing cardiac defect, whether it is mitral or aortic, whether due to hypertension or to emphysema. The outline and size of the heart, however, are not necessarily a measure of its functional capacity; in order to estimate this the hilus, the vessels and the appearance of the lung must be examined simultaneously. Enlargement of the hilus over 13 mm. with simultaneous enlargement of the vessels and, under certain conditions, of the pulmonary arch vindicates the existence of stasis in the pulmonary circulation; that is, it signifies beginning cardiac insufficiency. The type of branching of the vascular system is of importance for the course of the pulmonary stasis. Anatomically verified roentgenologic studies revealed that two types of branching predominate, the tree type and the shrub type, which may be combined in a mixed type. These various types show a different behavior in the presence of cardiac stasis. In the presence of the tree type of branching, stasis develops late and is of a mild degree because the vessels, owing to their width and expansibility, safeguard good canalization and drainage. However, in cases of the shrub type stasis begins early. In the course of stasis there first develops an acute engorgement, which appears either as a diffuse veiling of the entire lung, recognizable by the uniform turbidity and the blurred outline, or it is more superficial in the median and lower fields of the lung or more focus-like, as near the hilus, at vascular bifurcations, around pleural indurations, foci of hemosiderin and proliferations of connective tissue. Chronic pulmonary stasis develops gradually from acute cardiac stasis or from repeated acute exacerbations of stasis. The deposits of hemosiderin and the connective tissue appear in the roentgenogram as more or less nodular foci, which are located chiefly in the middle and lower fields of the lung. Repeated roentgenograms in the course of the years reveal that these foci gradually increase in size and density, and finally metaplasia into bone tissue may take place.

Effect of BCG Vaccine in Children.—Tsimbler and his associates studied the effects of Calmette vaccine on seventy-four children of ages ranging from 1 month to 3 years. The observations were carried out in a closed institution (home for infants) permitting systematic observations and rigid exclusion of all sources of exposure to tuberculosis. All the children in the institute were submitted to the Pirquet and Mantoux tests and to a clinical and x-ray examination. Stomach washings of the children to be given the vaccine were injected into guinea pigs. Some of the children received the vaccine by mouth in doses of 2 cc. (0.01 Gm. of the culture) every other day for three doses. Others were given injections of the vaccine either in a single dose of 0.04 mg. or of 0.02 to 0.01 mg. either in one dose or in fractional doses. The feces of the children given the vaccine orally were found to contain numerous BCG bacilli up to the eighth day. The authors did not find any deviation from the normal or any manifestation of a general reaction such as a rise in temperature or a gastrointestinal upset in any of the vaccinated children. The blood picture during the first to the ninth day showed in some an increase in the histomonocytic group, in others an increase in the neutrophils at the expense of the segmented leukocytes, and in still others no change. Cervical adenopathy was noted in a number of children, both those given vaccine and those not given vaccine, but this probably was due to an infection of the throat and the skin. Systematic monthly Pirquet tests proved to be invariably negative in the children given vaccine. On the other hand, the intradermal Mantoux test was positive in 72 per cent. This reaction may become weaker, disappear or remain constant but it is never accompanied by the development of a pronounced tuberculin allergy (Pirquet). No difference was noted in the reactivity of the two groups to the Mantoux test. Interpretation of roentgenologic studies presented great difficulties in distin-

guishing between signs due to grip infections and those caused by the vaccine. Such roentgenologic signs as were considered to be due to the effect of the vaccine were characterized by the enlargement of the peritracheal lymph nodes on the right side. The authors conclude that the differentiation between an infection with virulent bacilli and the syndrome produced by BCG vaccine (the *bécégitis* of the French authors) is difficult but possible on the basis of the development of a characteristic tuberculin allergy and the reversible roentgenologic signs which reflect a certain virulence, rather than pathogenicity, of BCG. The tuberculin allergy is manifested by an intradermal reaction and the absence of dermal reaction.

Cholesteatoma of Pia Mater: Two Cases. G. P. Frets.—p. 2615.

Treatment in Molar Pregnancy.—Stroink reports observations in thirty-five cases of molar pregnancy and twelve cases of chorionepithelioma. Of the thirty-five patients with molar pregnancy, twenty-eight were admitted to the clinic before expulsion of the mole and seven thereafter. The treatment employed for molar pregnancy at the author's clinic was generally conservative; that is, in twenty-four of the twenty-eight cases an expectant attitude was assumed. In two of these, 8.3 per cent, chorionepithelioma developed. This percentage is not higher than the average reported in the literature after molar pregnancy. In the cases in which chorionepithelioma developed, it readily yielded to treatment. Chorionepithelioma could be diagnosed early by means of curettage and the repeated control of the urine by means of the Aschheim-Zondek reaction. Regarding the therapy of chorionepithelioma, the author says that, in addition to surgical treatment, roentgen therapy is helpful. Roentgen therapy alone can be employed only if the tumor is not too large. When the tumor is already quite large, surgical treatment is also necessary; metastases yield rapidly to roentgen rays. Thus the prognosis of chorionepithelioma after molar pregnancy is much improved. However, in the cases in which chorionepithelioma developed after abortion or normal pregnancy the prognosis was much less favorable because the diagnosis was made too late.

Hypersensitivity to Insulin in Patients with Pellagra.—Mainzer directs attention to the fact that pellagra and Addison's disease have many factors in common and that, in many cases of pellagra, anatomic lesions of the adrenal cortex are demonstrable. Whereas studies have been made on the role of the adrenocortical hormone in the resorption of fat and on the relation between vitamin B₂ and the adrenocortical hormone, little attention has so far been given to the functional disturbance of the adrenals in relation to the behavior of the carbohydrate metabolism in pellagra. The author observed twenty-one patients with pellagra during the years from 1936 to 1938 and in sixteen of them he studied the behavior of the blood sugar curve following the subcutaneous administration of 5 units of insulin. He observed an abnormally severe

reaction, that is, there was an unusually deep and prolonged decrease of the blood sugar; moreover, observations for a period of five hours revealed that the subsequent elevation was retarded or completely missing. In several cases this small quantity of insulin produced severe hypoglycemic shocks and in one the disturbances lasted several days. This abnormal reaction persisted even after clinical improvement or cure of the pellagra. Thus it can be ruled out that the manifestation is caused by the previous malnutrition of the patient and it seems unlikely that a connection exists with a deficiency in the vitamin B complex. The persistence of the pathologic reaction after the disappearance of the signs of pellagra under suitable nutritional therapy makes such connections impossible. Involvement of the liver, of the anterior lobe of the hypophysis or of the thyroid seem improbable, in view of the observations. However, all clinical and pathologic anatomic factors indicate that a functional failure of the adrenals, which are impaired in patients with pellagra, is the cause of the hypersensitivity to insulin. Since the hormone of the adrenal cortex is indispensable for the resorption of a large number of substances, it becomes understandable that an impairment of the adrenals for the resorption of the pellagra protective factor (nicotinic acid-amide) leads to a vicious circle, which is the cause of the clinical relapses and of the incurability of advanced cases by exclusive dietetic therapy. It remains undecided whether a functional weakness of the adrenals represents a factor in the constitutional susceptibility for pellagra.

Neurogenic Heart Lesions.—Von Bonsdorff discusses the myopathies and neuromuscular disturbances, diseases of the peripheral nerves, diseases of the spinal cord and medulla oblongata and diseases of the brain. His observations indicate that heart changes are often observed in connection with nervous diseases, especially those involving the gray matter. Lesions in the gastrointestinal tract, especially peptic ulcers, can in many cases be traced to the autonomic nervous system, as was pointed out by von Bergmann and his associates. Moreover, Cushing observed cases of perforating ulcers in cases of brain tumor and relates them to a central increase in the tonus of the vagus and says that the same causes give rise to extensive gastric malacias, which are often observed in disorders of the brain. The neurogenic heart lesions can be regarded as a phenomenon parallel to these gastrointestinal disorders. In some of the cases reported by the author, lesions were observed in both the heart and the gastrointestinal tract. Regarding the morphologic nature of the neurogenic heart lesions, the author says that subendocardial hemorrhages, preferably localized in the ramifications of the conduction system in the intraventricular septum, seem to be typical of these conditions. They have been observed with increased brain pressure, with processes which affect the cervical portion of the vagus, with epilepsy and with encephalitis, eclampsia and paralysis agitans. Subendocardial hemorrhages can be produced experimentally by stimulating the cervical vagus or by administering parasympatheticomimetic substances. Regressive changes in the muscle fibers, consisting of hyaline and fatty degeneration, vacuolization and finally disappearance of the nuclei and fibrils have been observed in poliomyelitis, brain tumors, Friedreich's ataxia and so on. They often appear in scattered foci and may be combined with subendocardial hemorrhages and interstitial increase of cells. Observations in animal experiments favor the opinion that such changes can really arise neurogenically and that therefore there need be no question of chance coincidence of lesions of infectious or atherosclerotic origin. Both experimental and clinical experience indicate that occlusion of branches of the coronary arteries accompanied by myocardial functions can be due to neurogenic causes. It is not possible to state definitely in which manner the harmful nervous impulses attack the heart, but it appears that it is most frequently a question of abnormally strong stimulation of the inhibiting vagal nerves or of an increased activity of the parasympatheticomimetic humoral factors. Regarding the clinical importance of neurogenic heart disease, the author says that the neurogenic cardiac injuries are usually terminal phenomena. They might help explain many cases of unexpected "heart deaths."

THE RESTRICTION OF THE CORONARY FLOW AS A GENERAL FACTOR IN HEART FAILURE

CHAIRMAN'S ADDRESS

M. B. VISSCHER, M.D.

MINNEAPOLIS

An adequate supply of blood to maintain normal respiration of the cardiac musculature is the first requirement for a functionally normal heart. The ability of the heart to increase its work output in exercise and under other circumstances depends first and foremost on the capacity of the coronary system to supply blood to the heart muscle.

Only the strictly coronary types of heart failure are due to inadequate coronary flow as a first cause, but, as will be more apparent later, in all forms of progressive failure the restrictions in the total possible coronary flow limit the work capacity and therefore the life of the heart and in the last instance of the patient. So long as the oxygen supply to the heart can increase with its needs, that organ can continue to function, barring ventricular fibrillation, although it may function very inefficiently and waste a large share of its energy; but when the oxygen supply cannot keep pace with the need for it a rapid downhill course is described.

It has been the greater share of interest in the coronary circulation in heart disease has centered around the problems of closure of certain of the coronary vessels. These are the most dramatic episodes in which the coronary vascular system is involved, but there are other equally important alterations in the coronary blood supply which deserve attention and form the basis of this discussion. These other mechanisms are of two sorts. The first is a gradual and progressive narrowing or closure of coronary vessels with a concurrent decrease in blood supply to the musculature of the heart, and the second is the restriction in the coronary flow produced by elevations in pressure in those cavities into which the coronary venous blood drains.

There are certain aspects of the progressive coronary closure problem which are amenable to experimental study. Since this problem is of great interest it will be considered first. It is difficult to reproduce exactly the conditions occurring in progressive coronary sclerosis in adequately controlled physiologic experiments. Numerous studies have been made of the effect of completely closing by ligature or by sclerosing solutions larger or smaller areas of the coronary vascular

bed. These procedures imitate to a degree the conditions existing in acute coronary thrombosis but they do not shed any light on the effects of gradual occlusion of the coronary bed.

However, experiments with drugs which have specific coronary constrictor action have a bearing in this connection. It was shown by Melville and Stehle¹ and has been confirmed by others, including myself, that the pitressin component of the posterior pituitary has a powerful coronary constrictor effect. We have found that as little as 0.01 cc. of pitressin per kilogram of body weight injected intravenously into the dog reduces the flow through the coronary arteries as much as 80 per cent. It is of interest to note the consequences of this coronary constriction on the dynamics of heart muscle. If one measures the volume of the ventricles of the dog's heart in the heart-lung preparation, one finds that, if the work of the heart is kept constant, the addition of very small quantities of pitressin produces a great increase in the diastolic ventricular volume. This increase in the diastolic ventricular size is a reflection of what might be called the weakness of the heart muscle. The heart dilates only when it is unable to carry its load without so doing. It is well known that the energy output of the heart muscle depends on diastolic fiber length and that when a heart dilates under constant load that dilatation is due to the fact that the ventricle is unable to eject as much blood per beat as is delivered to it, and therefore increasingly larger quantities of residual blood remain within the ventricle at the end of systole. If the quantity which enters during filling remains the same, the diastolic ventricular volume must progressively increase until such a state is reached in which enough energy can be put to useful work by the contracting ventricle to eject a quantity of blood in systole exactly equal to that delivered to it in diastole. Thus it may be said that, when a heart dilates, a compensatory mechanism is being brought into play since the progressive distention of the ventricles results directly in an increased energy liberation in systole.

Now in the case of the ventricular dilatation under the influence of pitressin we have to deal, it would seem, with a heart muscle which has become less capable of doing work because it is working under partially anaerobic conditions. Its blood supply, and consequently its oxygen supply, is diminished and an oxygen debt develops.

The alternative to the view that decreased oxygen supply leads to diminished efficiency is that the completely anoxic heart muscle is unable to liberate energy for any considerable period and that therefore the heart as a whole becomes less able to do work when parts

of its musculature are inadequately supplied with oxygen. As far as the practical consequences are concerned, the argument on this point is of but little importance, because in any case it is universally agreed that when the heart muscle is partially anoxic it becomes less capable of doing work and that, when it is completely anoxic, after a short time it is unable to do any work at all.

Chart 1.—Partition of coronary venous flow between the thebesian veins and the coronary sinus in relation to pressure gradients.

The effect of pitressin seems to imitate quite closely over a short period of time the changes that occur with longer duration when the coronary arterial channels are narrowed by arteriosclerosis. The main interest in the observations on pitressin surround the fact that the ventricular dilatation of coronary sclerosis can thus be reproduced.

A lucky misfortune provided me with an opportunity to study the influence of another kind of coronary occlusion on cardiodynamic phenomena. In some work on the metabolism of the completely isolated mammalian heart it was necessary to employ an artificial oxygenator in place of the lungs. Consequently, following the instructions of Bayliss, Fee and Ogden, in meticulous detail, my associates and I built an oxygenator out of cast aluminum. On passing blood which had gone through this oxygenator through the completely isolated dog's heart, we found that the coronary flow progressively diminished and that the heart dilated rapidly so that within from thirty to ninety minutes it was enormously distended and unable to eject any blood, and ventricular fibrillation ensued. On analysis of the possible reasons for this rapidly progressive failure, we² found what might have been predicted, that aluminum hydroxide was formed when blood came in contact with aluminum metal and that the same kind of rapid failure could be reproduced by the introduction of from 100 to 200 mg. of aluminum hydroxide in colloidal suspension in physiologic solution of sodium chloride into the blood supplying the left side of the heart and thus the coronary vessels. Aluminum hydroxide in much higher concentration has no unfavorable effect on the contraction of the amphibian heart, in which there is no coronary system, and it has no deleterious effect when added to salt solutions entirely free from blood perfusing the rabbit's heart in a Langendorff preparation. It is of incidental

interest to note that when such colloidal aluminum hydroxide is introduced into the circulatory system in such a way that it has to pass through the lung capillaries before reaching the left side of the heart it likewise has no observable effect on the heart. The pulmonary capillaries or arterioles apparently serve as very effective filters for the particles which appear to be responsible for the closure of the smaller coronary vessels with resulting restriction in coronary flow.

The formation of aluminum hydroxide by corrosion in the heart oxygenator was perhaps a misfortune as far as the experiments for which the oxygenator was built were concerned, but the mishap provided us with a method by which we might study the effects of progressive coronary closure of this type on the dynamics of the heart muscle. It was found first of all, as already noted, that the heart dilated very rapidly and measurements of oxygen consumption and work showed that the energy liberation fell off greatly, indicating that in this particular situation some regions of heart muscle which were not supplied with any oxygen at all became effectively nonfunctional. The efficiency of the heart as a whole declines but not nearly so much as would have been anticipated from the enormous size of the ventricles. Thus we see that, when cardiac dilatation is essentially the result of restriction in the coronary blood flow, the heart muscle is unable to liberate as much energy in contraction as it could when the blood flow was normal.

There are undoubtedly regions between points of complete anoxia and of fairly normal oxygen supply where the situation is intermediate. In these regions in the heart muscle the properties of rhythmicity and conductivity as well as work capacity are altered, and some of the disorders of excitation and conduction in situ-

Chart 2.—Relative oxygen yield of coronary sinus and thebesian venous blood in relation to pressure and flow factors.

ations in which the coronary flow is restricted, but not cut off, as evidenced by changes in the electrocardiogram, are due to the situation which is described.

There has been a somewhat prolonged controversy between two groups of workers as to the essential changes in cardiodynamics in the failing heart. One group, including Ruhl and Katz and their collaborators, has held that in all types of failure the essential change is simply a decrease in energy liberation in contraction. The contrary view, to which I subscribe, is that, unless

2. Beland, J. L.; Moe, G. K., and Visscher, M. B.: Use of Aluminum Metal in Contact with Blood in Perfusion Systems, *Proc. Soc. Exper. Biol. & Med.* 39: 145 (Oct.) 1938.

there is a restriction in coronary blood flow to certain parts of the myocardium, spontaneous failure is associated simply with a decrease in the proportion of energy put to useful work, that is, in engineering terms, the mechanical efficiency. That this occurs has been shown by numerous investigators using amphibian hearts without coronary circulation and various species of mammalian hearts under a variety of conditions.³ The proponents of the first theory have based their conclusions mainly on observations on the mammalian heart working under conditions or using unsound energy.

It is my opinion that those investigators with the completely isolated heart in which the coronary blood flow was progressively declining were studying mainly failure due to coronary occlusion. This opinion is based on the fact that in my own experience their results can be duplicated only when the coronary blood flow diminishes for one reason or another. However, this is a very important type of failure and deserves careful study because of its importance to clinical problems.

The second type of mechanism controlling flow which must be considered in connection with the coronary blood flow in the failing heart has been referred to as the pressure gradient mechanism. It is on this point that we have conducted a considerable number of experiments within the past year in order to determine which factors are of greatest importance in this connection. We have worked with the completely isolated dog heart fed blood from a reservoir after passing it through an artificial oxygenator the surfaces of which were carefully lacquered to prevent contact of blood with material which might corrode and obscure the results. We have in general collected one fraction of the venous blood with a suitable cannula fixed in the coronary sinus and have collected that fraction of the coronary venous blood which enters the right side of the heart via the thebesian veins by allowing the right ventricle to pump this blood against an artificial resistance through a stromuhr. No other blood was allowed to enter the right side of the heart. The left side of the heart was fed through a cannula in the left antrum, and the ventricle was made to pump against an artificial resistance of the type usual in the heart-lung preparation. Thus the arterial pressure could be varied at will and the pressure within the right side of the heart could likewise be controlled, and by fixing the level of the coronary sinus outflow tube the sinus pressure could also be controlled. Experiments of this sort have been performed previously by Katz and by Johnson and Wiggers,⁴ but in neither case were all conditions appropriate for the demonstration of the relationships which we desired to study. In the experiments of Katz, the coronary arteries were fed from a system whose pressure was fixed arbitrarily, and in the experiments of Johnson and Wiggers the thebesian blood flow was not measured.

The flow of coronary blood, like any other fluid in a hydraulic system, depends on the existence of a pressure gradient. This pressure gradient, so far as the coronary system is concerned, is measured by the differences in pressure between the aorta, that is the orifices of the coronary arteries, and the coronary sinus and right ventricle. The importance of this pressure gradient in determining the coronary blood flow has not

been given adequate attention. It will be pointed out in the course of this paper that these differences in pressure are of the highest importance and must be reckoned with if one is to understand the pathologic physiology of clinical heart failure.

The results of a typical experiment by Moe, Wood, Keys and Visscher⁵ are shown in chart 1. Here the percentage of the total coronary flow emerging from the sinus is plotted against the pressure difference between the aorta and the coronary sinus. These values were measured at a series of five values for the aorta-pulmonary artery pressure difference. It will be noted that the greater the aorta-pulmonary artery pressure difference the greater the thebesian flow and the less the coronary sinus flow. When the aorta-pulmonary artery pressure head is less than 60 mm. of mercury the thebesian flow falls off greatly. The aorta-coronary

Partition of Total Outflow from Each Coronary Artery

Artery	Drainage	Per Cent Average
Left circumflex.....	Coronary sinus.....	38
	Right thebesian.....	48
	Left thebesian.....	14

Right circumflex.....	Coronary sinus.....	1
	Right thebesian.....	92
	Left thebesian.....	7

From Katz, Jochim and Weinstein.⁶

sinus pressure difference likewise has a determining influence on the partition. The higher the aorta-coronary sinus pressure difference, other factors being held constant, the greater the coronary sinus flow.

The effects of this relationship can be made clearer by showing their effect on the contribution made by each fraction to the oxygen used by the heart. In chart 2, from the same authors, are shown the inverse relationship between oxygen yield and volume flow through each channel. From this experiment and from others like it, one can observe that when the pulmonary pressure rises, thus restricting the thebesian flow, the oxygen content of the thebesian venous blood becomes consistently less than that of the coronary sinus blood. Thus the parts of the heart muscle which have to obtain their oxygen from blood emptying into the thebesian channels on the right side will be relatively anoxic.

It is of interest to note which portions of the heart will be so affected. Katz, Jochim and Weinstein⁶ have shown, as recorded in the accompanying table, that the right circumflex coronary artery, which supplies mainly the right ventricular muscle, drains almost exclusively, 92 per cent on the average, through the right thebesian system into the right side of the heart. Thus it is obvious that the right ventricle will be most seriously affected by a restriction in thebesian flow.

The left heart thebesian flow is of considerably less importance. Approximately 10 per cent of the coronary blood drains through these channels, and our observations show that about 7 per cent of the total oxygen used by the heart is yielded by left thebesian blood. Therefore elevations in left intraventricular pressure will have little direct effect on coronary blood flow by this mechanism. Of course, indirectly, through the

6. Katz, L. N.; Jochim, K., and Weinstein, William: The Distribution of the Coronary Blood Flow, *Am. J. Physiol.* 122: 252 (April) 1938.

effect on aortic and coronary arterial pressure, the coronary flow is majorly determined by the pressure the left ventricle develops. The left ventricle develops the head of pressure for coronary flow and its importance is inverse to the right ventricular pressure.

Blood can leave thebesian channels into the left ventricle only during diastole, because only then is the pressure gradient suitable, but flow can occur into the right ventricle both in systole and in diastole because there is a positive pressure gradient at all times. Increases in right ventricular pressure are therefore doubly important to coronary outflow.

The restriction in right thebesian flow observed when the pulmonary arterial pressure is increased seems to be due to two factors. First the flow is apparently decreased during systole because the pressure head is diminished, and second the flow also probably diminishes in diastole because the right ventricle does not empty itself as completely in systole and the subsequent diastolic intraventricular pressure is elevated above what it would be with lower pulmonary artery pressures.

The observations on coronary flow and oxygen yield are of interest in their own right and permit one to make certain probable deductions of clinical importance, as have already been intimated; but the more critical demonstration of their importance must rest on observations on the effects of coronary pressure gradient changes on the processes of failure itself. Experiments have been performed with the dog's heart in which the rate of dilatation of the ventricles was studied at several values of pulmonary arterial pressure. The results of a typical experiment are given in chart 3. The procedure was to measure the rate of dilatation with a Henderson cardiometer. Isolated hearts show a slow progressive dilatation which has previously been sub-

Chart 3.—The rate of spontaneous ventricular dilatation (failure) as determined by time and the pressure factors controlling thebesian flow.

jected to careful study under other circumstances by Peters and Visscher.⁷ The rate of this failure was measured at progressively increasing pulmonary arterial pressures. Over the course of several hours, three series of observations were made. The numbers alongside each point on the chart indicate the sequence in which the observations were made. It will be obvious that the rate of failure in this preparation is a definite function of the pulmonary pressure and that, as the

experiment proceeds, the deleterious effects of high pulmonary pressure are aggravated enormously.

Thus the direct experiment proves that elevation in right intraventricular pressure is a factor accelerating failure, and it seems most likely that this effect depends on the restriction in coronary flow which occurs.

In conclusion I should like to point out again the familiar fact that the left side of the heart can carry enormous loads, as in hypertension and in valvular disease, for many years, whereas when the right ventricle works against increased loads the heart fails rapidly.⁸ The physiologic mechanism of this important difference between the adaptive capacities of the two ventricles seems to be bound up primarily with the differences in the effects of elevated intraventricular pressures in the two sides of the heart on coronary flow. Independent of all other factors, the decreases in the coronary vascular pressure gradients produced by elevations of either right atrial (coronary sinus) or right intraventricular (thebesian) pressures have directly deleterious effects on the work capacity of the heart, greatly increasing the rate of failure.

DIAGNOSIS AND TREATMENT OF DISEASES OF THE EAR IN CHILDREN

HORACE JAMES WILLIAMS, M.D.
GERMANTOWN, PHILADELPHIA

The highest percentage of both catarrhal and suppurative otitis media occurs in children before the fifth year and it is obvious that, if progress is to be made in the prevention of deafness, emphasis must be placed on the diagnosis and treatment of otitis media in this age group.

For the sake of clarity let the age of infancy be up to 1 year. At that age the anatomy of the ear differs from that of the older child.

The auditory tube is short, being from 16 to 18 mm. long, but the breadth is equal to that of the adult. The pharyngeal orifice is on a level with the floor of the nose, and infected material consequently from the nose finds easy access to the tube. There is no angle or isthmus, and the tube is practically horizontal. The muscles are not well developed.

In the infant the tympanic membrane is thicker and more elastic than in the older child. The membrane often bulges when the infant cries.

The external ear also differs. The osseous external auditory canal consists only of a bony ring which gradually grows outward by the deposit of bone on its outer surface. The drum is almost horizontal and the walls of the membranocartilaginous portion are studded with fine hairs, which make examination of the tympanic membrane difficult.

During the second year the osseous canal begins to assume the adult form. The lumen of the canal becomes larger, and the tympanic membrane becomes more hori-

8. It has been noted by S. A. Levine (Clinical Heart Disease, Philadelphia, W. B. Saunders Company, 1936, p. 65) that patients with mitral stenosis have a better life expectancy if there is a coincident hypertension. It will be evident from the observations here reported that elevated aortic pressure will increase the coronary flow through the right ventricle. Since mitral stenosis leads to right heart failure, and improved coronary flow would logically be expected to delay such failure, the hypertension might exert its favorable effect through this mechanism.

Read before the joint meeting of the Section on Laryngology, Otolaryngology and Rhinology and the Section on Pediatrics at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 19, 1939.

7. Peters H. C., and Visscher, M. B.: The Energy Metabolism of the Heart in Failure and the Influence of Drugs on It, *Am. Heart J.* 11: 273 (March) 1936.

zontal and more easy to examine. The auditory tube also begins to take on adult characteristics.

Of acute suppurative otitis media associated with acute infections of the upper respiratory tract and acute infectious diseases such as scarlet fever and measles, one sees two widely different forms depending on the rapidity of the invasion.

In the first form the invasion of the tympanic cavity by the infection accompanies the invasion of the nasopharynx by the infectious disease and the symptoms develop rapidly. There is a rise of temperature and the pain in the ear is severe. The tympanic membrane is red and bulging in the posterior half. If it is seen early and incised, a hiss is often heard as the air escapes from the tympanic cavity. When it is seen a few hours later and incised a serosanguineous fluid is released. The pain is usually relieved and the temperature begins to fall. The discharge is first sanguineous and then serosanguineous, and in forty-eight hours, if it has not subsided, it is purulent.

There are usually some rise and fall of the temperature and some tenderness over the mastoid for the first few days. After myringotomy these symptoms may subside, only to reappear after several days. In other cases they are continuous until the mastoid is drained. There is active leukocytosis. Early x-ray examination shows a change in the mucosa of the mastoid antrum and cells. After several days a change in the fundus of the canal takes place.

The second form comes on later during the course of the disease, in scarlet fever from the second to the sixth week. It is the result of an infection in the paranasal sinuses, and the discharge has gained access to the tympanic cavity through the auditory tube. The invasion may be accompanied by a rise in temperature and some pain, or it may develop so insidiously that the first sign is discharge on the pillow.

The infection which produces this type is usually of less virulence, and the mastoid antrum and cells are involved without pronounced symptoms, usually until they are more or less completely broken down. Swelling behind the ear may be the first symptom to suggest a surgical mastoid. Frequent inspection of the canal and drug will reveal a gradual increase in the sagging of the posterior-superior canal wall and obliteration of the angle between the drum and the canal wall, or there may be a nipple-like projection of the drum which invites incision but on incision shows only a swollen, edematous membrane.

Early free linear incision of the tympanic membrane is advocated. It relieves pain and is usually followed by a fall of temperature. Repeated incisions are seldom of value. The tympanic membrane which invites them is usually bulging in the posterior half, and the bulging is caused by a swollen edematous mucosa of the middle ear brought about by a low grade infection in the mastoid. On the other hand, incision of the membrane after rupture when the drainage is not sufficient is of distinct value.

When looking for original research material on otitis media one naturally turns to the hospital records of patients with scarlet fever and measles, and, as the otitis of scarlet fever and measles is reasonably representative of otitis in general, it may be of interest to consider a few statistics concerning this type.

A search was made of the records of 14,733 patients with scarlet fever for data on acute suppurative otitis

media, and it was found that 1,535 of them had had the condition and the number of ears involved was 2,186. Of these, 858 ears received myringotomy before the drum ruptured, and in 6.6 per cent of them surgical mastoiditis developed; 233 ears were incised after the tympanic membrane had ruptured, and in 7.7 per cent of them surgical mastoiditis developed; 1,095 ears ruptured without incision, and in 9.3 per cent of them surgical mastoiditis developed.¹

A similar study was made of 1,954 patients with measles. Of these, 427 patients had 651 suppurative ears. In 321 ears, myringotomy was performed before the drum ruptured, and surgical mastoiditis developed in 4.4 per cent. In thirty-six ears the drum was incised after it ruptured, and surgical mastoiditis developed in one. In 294 ears the drum ruptured and was not incised, and surgical mastoiditis developed in 11 per cent.²

From these figures the conclusion may be drawn that early myringotomy has a distinct tendency to prevent the development of surgical mastoiditis from otitis associated with scarlet fever and measles.

Those patients in whom otitis media develops early during an infection have frequently a tympanic membrane which requires incision when the patient is first seen by an otologist. When the condition has not reached this stage, attention should be directed toward reducing the inflammation in the eustachian tube, middle ear and nasopharynx.

In young children who are unable to clear the mucopus from the nose and nasopharynx, a small rubber catheter may be inserted into the nostril, with a syringe or other form of mild suction attached, for the removal of the secretions from the floor of the nose and nasopharynx.

The external auditory canal should be kept free of discharge to facilitate drainage.

At the present time sulfanilamide and sulfapyridine are used widely in the treatment of otitis media. The best results are obtained when *Streptococcus haemolyticus* or the *pneumococcus* is present.

A series of patients with acute suppurative otitis media and an equal number of controls were treated with sulfanilamide at the Philadelphia Hospital for Contagious Diseases. At the time this paper was written the histories of nineteen patients treated with sulfanilamide and twenty controls had reached the office and the patients had been discharged from the hospital. It was found that 17.1 days was the average duration of the otorrhea for those treated with sulfanilamide and 15.1 days for the controls. One patient was operated on for mastoiditis among those receiving sulfanilamide and none among the controls. I realize that this is a small number for comparison.

Two things are desired in treating suppurative otitis media, namely a dry ear and good hearing.

The presence of superfluous lymphoid tissue in the nasopharynx is a handicap to continuous good health of the ear.

Large, hypertrophied adenoids definitely predispose the patient to otitis media.

In the group of 1,535 patients with scarlet fever before mentioned in whom suppurative otitis media developed, 3.5 per cent had had their tonsils and adenoids removed before scarlet fever developed.

1. Williams, Horace J.: Otitis Media in Scarlet Fever, *Tr. Am. Laryng., Rhin. & Otol. Soc.*, 1932, pp. 247-256.

2. Williams, Horace J.: Acute Suppurative Otitis Media in Measles, *Ann. Otol., Rhin. & Laryng.* 44:956 (Dec.) 1935.

In a study of school children of Rochester, N. Y., Kaiser³ found that a child with well developed adenoids untreated until the age of 10 years will have an appreciable loss of hearing. His survey showed that the removal of lymphoid tissue offers considerable protection against infection of the ear during the susceptible age.

Crowe and Baylor⁴ have recently reported good results from the use of x-rays and radium in reducing the lymphoid tissue around the eustachian tube in children with impaired hearing.

Hoople and Cave⁵ in a series of 292 cases of scarlet fever brought out by x-ray examination the fact that 91 per cent showed sinus involvement, that each patient with purulent otitis media had involvement of the sinuses of that side and that no patient with normal sinuses had an aural complication.

Campbell⁶ observed the close association of sinusitis in children with purulent otitis media. He described sinusitis as the most common of all infantile diseases.

The chief factor in sinusitis producing otitis media is the accumulation of the nasal secretions in the nose and the nasopharynx. The acts of crying and vomiting force the secretions into the eustachian tube.

The administration of drops of various kinds has little effect, as they cannot reach the mucosa because of the abundant secretion covering it. This should be removed and its removal repeated as often as the secretion accumulates. Since infections in the sinuses are responsible for so large a proportion of suppurative otitis media, it is reasonable to suppose that it more frequently produces a less severe inflammatory reaction in the mucosa of the eustachian tube and tympanic cavity, which results in a thickening of the mucosa and obstruction. It is this type of inflammation which is the forerunner of impairment of hearing.

Ciocco⁷ reexamined 552 children who had been tested five years previously. His observations indicate that 25 per cent of the patients who presented slight impairment of hearing on the first examination showed on subsequent examination a greater impairment of the same type, that is, either loss for high tones or loss for the tones of the speech range. When there was marked impairment for either of these it did not often improve.

Deafness which develops as the result of adenoid tissue in close relation to the orifice of the eustachian tube or of a sinus infection keeping the mucosa of the eustachian tube and tympanic cavity inflamed is usually progressive. If the cause is not removed and the pathologic process continues for a long period, treatment is usually of little use.

CONCLUSIONS

1. The anatomy of the infant's ear predisposes to otitis media.
2. Sinusitis is a large factor in the production of otitis media.
3. Early myringotomy is a distinct advantage.
4. Impairment of hearing should be recognized and treated early.

ABSTRACT OF DISCUSSION

DR. DEAN M. LIERLE, Iowa City: Except for small deposits in the floor and niches, there is normally complete regression of the embryonic connective tissue in the tympanum and antrum of the infant at birth. According to Wittmaach and others, retardation of regression of this embryonic tissue may occur before birth, possibly because of mechanical irritation of foreign bodies, such as vernix or meconium, carried into the middle ear spaces with amniotic fluid. The degree is variable. In some cases there is complete lack of regression. In fact, it is impossible to say just how many tympanic cavities and antrums develop normally. Certainly there are too many which are pathologic. These, as Dr. Williams has shown, may be responsible for infection and delayed healing. On some occasions when I have done myringotomies, the drum when incised has felt like spongy tissue, only a small amount of purulent material escaping. Occasionally the tympanum may be dry but the antrum infected in children with so-called cholera infantum syndrome, particularly if the infection has been present for some time. These late cases require immediate antrotomy, following preliminary treatment to combat the marked dehydration accompanying the infection. Fortunately, most infants and young children respond to conservative methods of treatment, as has been suggested by Dr. Williams. The use of Haskins's suction is at times very valuable, provided care is taken to avoid trauma. Sulfanilamide has proved of great value. However, I am sure that at times myringotomies have been delayed too long when the drug is used.

DR. BORDEN S. VEEDER, St. Louis: It is difficult for me to associate sinusitis and otitis media as cause and effect. It is probably true that in a large number of cases of otitis media there is some involvement of the sinus, but I think that the two conditions are due to the same cause, that is a nose and throat infection, and the sinus becomes involved at the same time that there is an otitis media. I must question the evidence of x-ray plates that have a shadow as showing dependent relationship between otitis media and sinus infection. Perhaps even more important is the question of an early paracentesis. While Dr. Williams referred in his work chiefly to the scarlet fever group, in his conclusions he definitely stated that in otitis media an early incision of the drum is of advantage. I should not want to have a statement of that kind go out from the section without some one disagreeing with him. Certainly as far as young children and infants are concerned an early incision is often of decided disadvantage. The pediatricians see a tremendous number of patients with otitis media not referred to the otolaryngologists because they take care of themselves. I checked up my records rather roughly over this last winter and about 80 per cent of the cases of otitis media cleared up without any incision. An important study of otitis media has been that of Dr. Bakwin and the staff of the Pediatric Department of Bellevue Hospital. They feel that too many examinations, carelessness in examination and too early incision lead to purulent otitis media. By not allowing any one with a respiratory infection to make an otoscopic examination, by careful technic and by infrequent examinations they have strikingly reduced the incidence of otitis media in the wards of Bellevue Hospital. In the three year period 1931 to 1933 the incidence of otitis media in all infants admitted was 23.3 per cent. During the period when these regulations were in effect, from 1934 to 1938, only 8.9 per cent developed. A great deal could be done in hospitals by careful regulations, infrequent examination and the avoidance of respiratory infection. So far as sulfanilamide and sulfapyridine are concerned, I think we must keep our fingers crossed. Not only have I seen a number of pediatricians and otologists giving a few grains to patients with upper respiratory infections which could not have any effect whatever, but there certainly is a masking of symptoms at times. It will take several years of careful work before we can judge of the value of sulfanilamide therapy in otitis media.

DR. CHARLES HENDEE SMITH, New York: The otologic fraction of this audience will shudder when I say it is impossible to examine the small baby's ear properly with a head

mirror and speculum. One cannot see a baby's ear drum with a speculum and a head mirror as well as one can with a good otoscope. It is impossible to hold a small baby upright and look at the ear. I have the baby laid flat on the bed. The mother spreads his arms. I take his thighs between my knees and then the baby is helpless. In the Children's Service of Bellevue we have a definite set of rules. The child who comes in with a red eardrum is treated for twenty-four hours with epinephrine or ephedrine in the nose instilled once an hour. Between treatments the affected ear is kept uppermost. If the short process is not visible in twenty-four hours, a myringotomy is done. In exceptional cases this period is reduced to twelve hours. Fever is no guide, because the fever comes from the infection which causes the otitis as often as it does from the otitis. The second indication is spontaneous rupture. The man who lets a drum burst and run is riding for a fall. The rupture is small and high up, the drainage is poor and those are the cases in which I see the most trouble, mastoiditis petrositis and impaired hearing later. Pain is no guide; it is over in from four to eight hours. Incision is sometimes necessary. If one thinks of the diameter of a baby's drum, a few millimeters across, and realizes the length of the incision, it is obvious that it may heal partially just as any wound does, even though it is discharging. We allow one reincision, usually not before eight to ten days. Our indications for mastoid operation are persistent or recurring fever, a discharge which becomes more profuse after the fourth or fifth day, and what I call the mastoid test. I am sure that too many drums were incised. I am sure also that in those years there were worse respiratory infections than there were in succeeding ones. Our experience with sulfanilamide has been that of Dr. Williams. We have not been able to abort otitis media with sulfanilamide or sulfapyridine. We are seeing in New York a great deal of harm done by the treatment of otitis media with these drugs. Cases are allowed to go on which need paracentesis or a mastoid operation, and a deep complication develops in some of these.

DR. CLIFFORD SWEET, Oakland, Calif.: I believe that head mirrors are better than any otoscope that was ever made, if they are properly used, and if any one is going to do a good myringotomy he can't do it through an otoscope. The method of holding a child as outlined by Dr. Smith has its dangers. I have one that is perfectly safe, even though the child should urinate. I have the child lie down on the bed and his mother sit on the bed beside him, and if he is the kind that is going to use his legs she need only put her arms across his legs just above his knees and then take one of his hands in each of hers and put them behind the midline of his body. At first if the mother does not hold the child's hands but holds him by the elbows his hands will come up and hit you. If the child resists when you attempt to turn his head to one side, bring his head suddenly forward into full flexion, and you can then turn his head easily to either side. The power of resistance to lateral rotation of the head is reduced to a minimum with the head in full flexion. Having turned his head in this manner, put the heel of your hand with which you hold the ear speculum on his head so that if he happens to move suddenly your hand takes the impact of his head and you don't cut his ear canal or damage it with the ear speculum. It is also important to remove wax from a child's ear canal gently without producing trauma. I learned from Dr. Roy Nelson of Oakland something which has been useful as an indication of whether or not one should do a paracentesis. If the child is old enough to understand and you have gotten his cooperation, you can tell a great deal about the state of his middle ear by determining his ability to hear. I don't care what the drum looks like; if a child can hear up to 50 per cent or more by comparison with his opposite uninvolved ear or with my own by means of the tick of my watch, I let his ear alone and come back the next day and usually find it all right. It is often difficult to differentiate between an otitis media and a myringitis. A myringitis is usually far more painful than otitis media. If the child's hearing is unimpaired or almost so, he hasn't a middle ear that needs surgical relief but has myringitis that should be left alone to take care of itself.

DR. E. LEE MYERS, St. Louis: No one can be dogmatic on the question of ears. Those who have had considerable experience in whether or not a young child should be operated on oftentimes are humiliated, especially when we have a pediatrician in consultation. Many a time I have seen a case and called up the pediatrician and said to him "I can't see any indications to operate here," to ascertain later that the ear drum had burst within a short time. There have been occasions when I have wanted to operate and the pediatrician refused to permit me to operate, and I found that he was right. When you are confronted with some of these children that can't breathe with their mouths when their noses are stopped up, you must do something. For a number of years I have used a 0.25 per cent solution of neosynephrin, preferably in isotonic solution. For my presbyopic patients I am using an otoscope and have no trouble in using it, although heretofore I was using a head mirror; hence one has to settle that question oneself.

DR. HORACE JAMES WILLIAMS, Philadelphia: When I mentioned sinusitis in relation to otitis media I was referring particularly to that which occurs in scarlet fever. In scarlet fever, otitis media may develop at any time of the disease from the first day to the last day of convalescence. When it develops early it is usually due to the scarlatinal infection but when it occurs later the sinus infection is responsible for it. In these late cases the otitic symptoms are not marked and a surgical mastoid often develops with extensive destruction of the mastoid process with but few symptoms. About myringotomy I am not radical when it comes to opening an ear. A prominent otologist told me that once he went to see a patient with a severe otitis media and told the mother that the ear had to be opened but the grandmother said "Not in my time have we ever had an ear opened." The next day when he returned the inflammation had subsided and there was no necessity for opening it. On many other occasions when he was on the verge of opening an ear and let it go, the ear had ruptured when he returned the following day. It is difficult to be sure when an inflammation is going to subside or when it is going to rupture. I am associated with a hospital where there is promiscuous opening of ears. A patient entering the receiving ward usually has a paracentesis if no reason can be found for the elevated temperature other than a pink tympanic membrane. Having escaped the intern in the receiving ward, the patient now encounters the intern on service in the children's ward, who opens one or both ears on the slightest provocation and reincises them if there is any evidence of inflammation and an unaccountable elevation of temperature. Should the patient be so fortunate as to escape and continues to have a low-grade fever from an unknown cause, he now encounters the pediatrician, who recommends opening of the drum. If the ears are not infected by the first incision they are subsequently, and they frequently proceed to a surgical condition. The question of opening the ear requires thought and a great deal of experience, and after one has had considerable experience one is going to let some ears go that ought to be opened, and he is still going to open some that would have gotten well without an incision.

A Barrier to Progress.—Research is widely exploited for professional ends; records of imperfect and actually unsound work find an almost open path to the printing press; reports of purely repetitive work have reached an extraordinary and most undesirable magnitude; many papers are republished almost in duplicate. The effect of such publication has passed beyond the bounds of menace; it has grown to form a distinct barrier to progress, with which more serious workers recognize they have to contend. The baneful effects are twofold. By its mass it conceals work that has value; by its quality it undermines the general standard of accuracy in observation and thought. Current teaching in the wards and textbooks, current methods of thought in practical daily work, are built in very large part on the basis of published articles, past and present. The quality of such articles is a matter of vital concern to professional work, both directly and also indirectly, through its influence on progress.—Lewis, Sir Thomas: *Research in Medicine and Other Addresses*, London, H. K. Lewis & Co., Ltd., 1939.

ABNORMALITIES OF THE EYE AND THEIR SIGNIFICANCE IN TRAFFIC COURT CASES

LOWELL S. SELLING, M.D., PH.D.

DETROIT

Although the Psychopathic Clinic of the Recorder's Court has been examining traffic offenders for fifteen years, the first clinic specially devised for the purpose of giving examinations in traffic cases was created in October 1936, when a special division of the recorder's court clinic was set up in connection with the traffic and ordinance division of that court. Because of the lack of definite information about what constituted a safe driver, it has been necessary for the traffic clinic to feel its way along and to abide by so-called standards until the present, when this paper raises some questions of whether the accepted standards are fair either to the driver being examined or to the public.

Soon after the creation of the traffic clinic I pointed out in a paper¹ that there were three ways in which the physician could be of value in assisting the authorities who are anxious to cut down mortality and morbidity due to traffic accidents. These were by detecting and correcting physical disorders, mental disorders (mild and severe) and disorders of vision. Because of my personal interest in the psychology of vision as well as my interest in neuro-ophthalmology, I found it necessary very early in the career of the clinic to investigate the various appliances which could be

Fig. 1.—The glarometer.

obtained and the standards which were presumed to be of importance in determining which drivers were possessed of safe vision and which were possessed of questionable or dangerously poor vision. It is a *sine qua non* that a person must see to operate a motor car. How well he should see has been set up by the Com-

mittee on Standards of the Section on Ophthalmology of the American Medical Association.²

There are four aspects of vision which must be considered: (1) the psychologic aspect, which includes the synthesis of visual sensation into perception and its modification by other psychologic functions such as impaired judgment, bad attitude and mental disease; (2) disorders of the refracting media of the eye and disorders of the extrinsic or intrinsic musculature; (3) organic disorders of retinal function, and (4) the physi-

Fig. 2.—Top elevation of the glarometer. In this and in figure 3 A indicates 300 watt lamp; B'B'', ground glass screen; C'C'', printed word; D, 100 watt lamp; E, rheostat.

cal aspect. I am unable in this report because of limited time to take up the first two and the fourth considerations, which are of great importance, so I will limit this presentation to a brief summary of our observations with regard to the retina.

METHODS USED BY THE CLINIC

In addition to the usual general physical, neurologic and ophthalmologic examinations, we include tests using special apparatus to determine depth perception, visual fatigue, judgment of speed and distance and other psychophysical tests in which vision plays an important part. Also tests are used by us to determine visual acuity, muscular balance and, what is most important in the present paper, a series of tests dealing with color vision, visual span or horizontal campimetry and glare sensitivity. Of course, an ophthalmoscopic examination is carried out in each case.

The present report deals with 716 persons who were given complete clinical examinations, forty-five control subjects secured from the public at large, who were not given psychiatric examinations, and a similar control group of minor violators consisting of 141 persons who were given the examination by choice instead of spending one day in jail for their traffic violations.

GLARE SENSITIVITY

One of the important physiologic problems confronting the ophthalmologist is the problem of photopic and scotopic vision. The capacity of the eye to function at night is one of extreme importance in the problem of traffic as distinguished from the usual problems which confront the ophthalmologist.

The patient is brought to the ophthalmologist under ordinary conditions because he is uncomfortable, has headaches or has trouble in seeing objects under artificial or natural illumination. The report of the National Safety Council for 1937³ reveals that between the hours of 6 p. m. and 6 a. m. 67.2 per cent, or two thirds, of the accidents occur. The reports of Jeghers⁴

Publication of the Psychopathic Clinic of the Recorder's Court, Detroit, Series, T-15.

and others would indicate that accidents may be due to vitamin A deficiency. Assuming that vitamin A deficiency does interfere with visual function and that rhodopsin is the critical substance in night vision, our glare-test statistics do not indicate that the vitamin A affect on glare vision can be demonstrated.

In a study of forty control cases we were unable to find that there was any marked distinction between the recoverability of a fatigued eye and the unfatigued eye in traffic violators and the control group. Sensitivity to glare was tested by a special apparatus consisting of a box divided in half by a screen of ground glass. The patient's eyes were 18 inches from the ground glass and he looked directly at it. In the half of the box behind the glass is contained a 300 watt lamp, which is adjusted to the place where the luminosity of the whole 24 inch square of glass is approximately equal (fig. 1). The patient is required to look at the ground glass screen on which a word in letters three-tenths inch high is placed. This represents approximately 20/60 vision, thus eliminating error due to reasonable lack of visual acuity. When the patient first looks in this apparatus he is subjected to an intensity of approximately 350 foot candles of light, which is cut down in ten equipotent one second intervals to complete darkness. He reads the word when he can. The range of

Fig. 3.—Side elevation of glaremeter.

the clinic cases extends from immediate perception of the word to inability to read it with light cut to a minimum, probably about 10 foot candles.

Tables 1 and 2 give the age distribution and the racial distribution in ten intervals for sixty-one subjects. It has been assumed that age is important, but the results shown in these tables do not convince me that the belief of Allgaier⁵ in this respect—that the glare sensitivity increases with age—is correct. In a comparison between white persons and Negroes, one can see that Negroes are much less sensitive to glare than the white person.

We divided our subjects into those with adequate and those with inadequate diets and we found that the average sensitivity to glare in the two groups was almost identical, the average being approximately 70 units. This would imply that the lack of butter and rich foods in the diet which might supply vitamin A is perhaps not necessarily responsible for collisions at night and that vitamin A research may be less important in the problem of night blindness than was thought. Because of the different results in Negroes and white persons, the amount of pigmentation in the retina is very likely of more importance.

FIELD OF VISION

One of the points which seems to interest the psychologist the most is the problem of the field of vision. One of the arguments presented by Lauer⁶ and De Silva⁷ is that the field of vision should be examined in order to determine whether a man is safe on the highway. They warned the public that there are many men who commit serious traffic violations who have

Fig. 4.—Traffic horizontal campimeter.

tunnel or gun-barrel vision. In the whole group of 716 persons passing through our clinic who were referred because of accidents, traffic violations, such as going through red lights and other forms of misconduct which might be due to the fact that they could not see properly out of the corners of their eyes, only five persons had less than 140 degree angles of vision for movement and all had corresponding visual fields for colors. In all five of these pathologic cases, with the exception of one special case in which the subject was sent in because he had been hit from the side three times (he was not brought into court; his examination was requested by his employer), definite neurologic disease was found. There were two with multiple

found the characteristic hysterical tunnel vision of the psychoneurotic.

Table 3 shows the average readings for the various colors in our two control groups, forty-five members of the general public, and 140 minor offenders. These results are expressed in inches, 57 inches being the distance from the target of the perimeter to the end of the rail carrying a small car (fig. 4).

Our special perimeter consists of a semicircular rail which is 1 meter equidistant from the chin rest, the target being directly in front, as it should be, and the rail extending 90 degrees to each side. The reason we use such a large perimeter is to eliminate defects in lighting and perhaps minor defects in the refracting media of the eye. Since illumination may bring the various color fields out to the periphery if there is too much light and restrict them if there is too little, it is possible, by having a large overhead light giving 60 watts of illumination at all points of the circle, to eliminate this error. We also give a realistic effect by having small cars on the track which the subjects describe as soon as they can see the color, shape or movement. These can be changed without the sub-

who were partially red-green blind. There were thirty-nine, or 5 per cent, who were red-green blind and one who was totally color blind. These were the results of the Ishihara test and the patients were checked on a traffic semaphore with adjustable lenses so that position error could be eliminated. All but three of the color blind could distinguish a red from a green light with ease. None of the color blind had serious traffic records. Only twelve had a record of going through a red light, while a much greater number of the "normal" had tickets for this offense. The three who could not make the distinction between the lights were found to be suffering in two cases from a severe degree of feeble-mindedness and in the third case from dementia paralytica. During presentation of clinic material to groups of drivers it was possible to find and check a number of color blind persons in the community, and reports are at hand of three drivers who have been given awards for safe driving during the past two years who are definitely red-green color blind and who have never had a ticket and have in several hundred thousand miles of driving not had an accident. The clinic is inclined to minimize the problem of color

ject's awareness of the change and provide a more accurate detection of the actual field than could be gained with the usual small perimeter, because the clinic perimeter eliminates psychologic errors due to cheating and overanxiety.

COLOR VISION

Last, but not least, a few words are needed about our observations in regard to color vision. It will be noted from table 3 that the color fields are substantially those which usually are found: the field for movement is greatest, that for blue next, that for red lowest and that for green between blue and red.

We were very much interested to find in our studies that of 716 subjects there were ten, or 1.3 per cent,

blindness and is doubtful whether it is important in driving a car safely. Certainly a color blind person can use clues as the position of the lights and the movement of other cars. Several color blind drivers have told us that they are able to make a distinction between traffic lights but cannot match colors in clothing, and their safe records bear out the idea that color blindness per se does not make a driver dangerous.

CONCLUSION

It can be said that the determination of the adequacy of retinal function is very important in deciding whether a man should drive a car. The matter of glare sensitivity remains up in the air, but apparently those with more pigmented retinas are less sensitive and diet may be less important than is now thought. Visual fields are seldom impaired, and color blindness does not necessarily interfere with a person's ability to drive a motor car.

I hope on some future occasion to be able to discuss our observations with regard to acuity and other visual functions and perhaps to enlarge on the retinal factors to a greater extent as our information is exemplified, but it is my belief that I have here indicated the need for clear thinking as regards the application of what is known about retinal function to the problem of the motor car operator.

330 Recorder's Court.

ABSTRACT OF DISCUSSION

DR. ARTHUR J. BEDELL, Albany, N. Y.: Organic disorders of retinal function, color vision, "visual span" and glare sensitivity are important phases of the ocular examination of automobile drivers. Dr. Selling confirmed my impression that vitamin A deficiency has no demonstrable effect on vision in the dark. Although his clinical apparatus does not simulate actual working or road driving conditions, his report is worthy of serious consideration; but, before enduring conclusions can be reached, it seems advisable to have as controls a much larger number of automobile drivers from several different localities. The author's observations on color defects are interesting and well substantiated by ophthalmologic experience. The intensity of light is frequently the guide by which a color blind auto operator distinguishes between the stop and go signals. I made contact with the New York State Bureau of Motor Vehicles to determine some of the ocular reasons for automobile accidents. I was permitted to check the reports which are being tabulated in the department at Albany. Eventually the segregated material will be of great assistance to those engaged in analyzing accidents as well as those working to prevent them. Perhaps the most important observation made from the New York State records is that drivers with markedly defective vision in one eye had an accident on the side with the better vision in 50 per cent of the cases. But here again the cross section of operators and accidents is too small even to predicate a suggestion of a statistical formula. The observations have a distinct bearing on the author's perimetric studies and conclusions and may lead to the intimation that the mental condition of the driver is one of the essential factors in safety. The work this section has done in outlining the visual requirements has met with widespread approval and the standards have been adopted by several states.

DR. ALBERT C. SNELL, Rochester, N. Y.: Dr. Selling has limited his discussion to retinal functions, especially to glare sensitivity. He states that the "solution is still up in the air." This statement is true for several reasons: 1. The term glare has not been precisely defined. 2. There is uncertainty as to the exact elements of the function of vision which are being tested by the glarometer. 3. There is no standard for glare sensitivity by which to determine the normal or efficient operator and the inefficient or dangerous operator. Glare might be defined as a disturbance of visual sensation caused by excessive aberrant rays of light. I am at a loss to know what physiologic function of vision is being measured or tested in the use of the so-called glarometer. We probably have here a test of the power of adaptation. But, since the test object is placed at the center of fixation and also of illumination, this test seems to be one of speed of recovery from retinal shock, fatigue or exhaustion for variable decreasing light intensities. The test is probably not that of adaptation of the macula, as this sense is absent here according to the belief of physiologists. The physiologists make a distinction between adaptation and fatigue. I wish that Dr. Selling could make clear the relation between adaptation, fatigue and glare. Evidently there is some relation between the adapted eye, contrast, the intensity of illumination, the length of exposure for various intensities, and the time period necessary for recovery of a normal visual function. It would be helpful if scientific workers could establish some definite formula by which all these factors would give a quantitative measurement by means of which glare sensitivity might be made practical for the determination of the individual's capacity or efficiency to operating a motor vehicle. Dr. Selling speaks of an "adequate function" but this is not defined. The test objects looked at in Dr. Selling's tests require an approximate visual acuity of 20/60. This low acuity destroys to some extent the value of the test, since visual acuity is acknowledged as an important factor in the individual's tolerance to glare. Glare tests should be made by means of a test character which corresponds to the individual's best acuity while wearing the proper correcting lenses. The complexity of the problem is obvious and still unsolved. For this reason the subject of glare was omitted from the report of the Committee on Visual Standards for Operators of Motor Vehicles which was submitted to this section last year. This committee found no standard for normal, no satisfactory instrument by which to measure glare sensitivity

or its recovery, and no standards for glare sensitivity by which an individual might be classed as a hazard in operating a motor vehicle.

DR. LOWELL S. SELLING, Detroit: I tried to limit my paper to testing the eyes of drivers, and both discussers have opened up rather vast fields which I feel I should not take into consideration at present. With reference to Dr. Bedell's comments I should like to state that we use a special perimeter for many reasons. With the standard perimeter, particularly, there are certain types of cheating, the flick of the eye which the observer occasionally misses. Also we are trying to eliminate the factor of visual acuity because I question the standards of visual acuity for drivers. This perimeter eliminates this factor by its 1 meter depth, to detect gross changes important to drivers rather than fine scotomas. Dr. Snell opens up a wide field. He is correct in raising the question of definition of glare. Our apparatus correlates about 0.62 with night accidents, a fact not presented in the paper because I do not think it is yet substantiated by a sufficient number of cases. This apparatus does simulate what goes on when a car comes at one with very bright lights. The subject reacts and the accident occurs while the retina is recovering, so that here we try to get some sort of measure of retinal recovery. The size of the word is not important; a symbol could be used. Visual acuity errata are eliminated by using a very large object which the light will penetrate at even low intensities and which is easy for the person to see. With regard to visual fields, other factors may be more important than physical condition; i. e., the type of hat worn by some women shuts off the vision of one eye and perhaps limits the other. With regard to glare, the mechanical factor such as the raising of the headlight beam by the weight of people in the back seat of a car may be more significant than physiologic observations.

AMPUTATION STUMPS OF THE
LOWER EXTREMITY

PAUL C. COLONNA, M.D.

AND

FREDERICK vom SAAL, M.D.

OKLAHOMA CITY

Our purpose in this paper is to report a study of seventy cases of amputation of the lower extremity. We will present the causes for amputation and the treatment received, as well as the present appearance and function of the amputation stumps.

This entire subject received great emphasis after the World War, at which time it has been estimated that more than one-half million amputations were done. Surgeons began analyzing their cases, and closer contact with the prosthesis makers emphasized many practical phases of the problem. As a result the rather well defined rules for stump lengths have been repeatedly stressed. This study will show that if these rules are violated reamputation frequently becomes necessary.

During the past nine years in the orthopedic service at the State University and Crippled Children's hospitals there have been more than 250 amputations, and for our follow-up study seventy patients returned. The average follow-up period was thirty-one months. Seventy-two per cent of the patients were males, which is probably accounted for by the fact that all the amputations due to trauma were performed on males. The age at amputation ranged between 4 and 76 years, but more than one half of the patients were between the ages of 10 and 20. Severe trauma was the reason for the largest number of operations and accounted for about 25 per cent of the total number; accidents in

which the patient was struck by a train predominated. Congenital deformities, such as absence of the tibia, absence of both bones of the leg or pseudarthrosis accounted for nine amputations, and infectious processes, such as some type of osteomyelitis, including tuberculosis, accounted for twelve. The presence of a

Fig. 1.—Molded leather socket for knee disarticulation.

malignant tumor accounted for sixteen, and vascular occlusion, such as diabetic, arteriosclerotic or postoperative thrombosis, for the remaining thirteen.

Generally speaking, one may say that an amputation may be considered whenever there is a reasonable certainty that an improvement in form or function will follow the operation. As a rule one should be much more loath to amputate in the upper than in the lower extremity, because of the generally unsatisfactory prosthesis for the upper extremity. The finer type of movement required of the non-weight bearing extremity is an obvious difficulty, for, in spite of the excellent contributions of Sauerbruch in Germany, Vanghetti in Italy and Kessler¹ in the United States by the cineplastic prosthesis, the average surgeon will amputate the upper extremity only as a last resort and then is extremely careful to obtain as long a stump as possible.

A severe injury to a limb through trauma may require immediate amputation, but a severe compound fracture is not in itself an indication for amputation. Every attempt should be made in the early treatment following severe injury or infection to save an extremity unless the crushing type of accident, or the type of infection, renders amputation a necessary, life-saving procedure. If severe shock is present the operation must be deferred, and in the interval blood transfusions and intravenous injections of saline solution should be employed.

An ideal stump should be conical and smaller than the opposite extremity. In the leg the amputation should be at the junction of the upper and middle thirds, and the stump thus varies between 4 and 8 inches in length, depending on the height of the patient. In the thigh it should include all available length above the condylar

flare. The skin, including the scar, should not be adherent to the bone. The scar may be anterior, posterior or at the end. The end of the bone is preferably covered by soft parts of not more than one-half inch in thickness. The bone should be amputated by the aperiosteal method described by Kirk,² and the ends should be rounded. Therefore there will be neither sharp edges nor spurs. In the leg the fibula should be cut $1\frac{1}{2}$ inches higher than the tibia. When the stump is shorter than 5 inches the fibula should be excised. The nerves should have been injected with alcohol.

The closed method of amputation, from which primary union is expected, was used in almost all of our cases, but there were a few guillotine amputations.

As for the operation, probably the most important decision is regarding the choice of amputation site. Beginning at the foot, operation through the metatarsals is permissible. We have a patient with a midmetatarsal amputation who has an excellent result because the insertions of all the important tendons remain and the foot is balanced. The Lisfranc and Chopart amputations, through the tarsometatarsal and mediotarsal articulations respectively, are rather generally condemned, both for the application of an efficient prosthesis and for weight bearing. An equinus foot nearly always results from either of these procedures. In this series there was one Chopart amputation, and the patient had a poor result because no satisfactory prosthesis could be fitted to the stump and because the skin frequently broke down over the end of the stump. Another patient had a transmalleolar amputation; some of the malleolar flare had been left and the tibia measured $14\frac{1}{2}$ inches. This stump remained healed only as long as the patient did not use his prosthesis but always ulcerated after a few days of weight bearing. The ankle appliance was very unsatisfactory, and he was admitted to the hospital

Fig. 2.—Short stump, with a movable painful fibula, which should have been excised.

for reamputation. When he was last seen a 7 inch tibial stump was giving him a satisfactory extremity. A tibial stump that is much shorter than 7 inches may be satisfactory, although it is not preferred. The shortest stump in this series measured $1\frac{1}{2}$ inches from the joint line to the end of the tibia, yet the knee motion was quite good. One girl had bilateral $2\frac{1}{2}$ inch tibial stumps and

1. Kessler, H. H.: *Am. J. Surg.* 31: 316 (Feb.) 1936; 43: 560 (Feb.) 1939.

2. Kirk, N. T., in Lewis, Dean: *Practice of Surgery*, Hagerstown, Md., W. F. Prior Company, Inc., 1930, vol. 3, chapter 10.

walked very well. However, she illustrated another point; that is, if the stump is shorter than 5 inches we have always found it necessary to excise the fibula. This was not done on either of these stumps originally and a second operation was necessary on each. Most of our knee disarticulations have been unsatisfactory

The Callander³ type of amputation just above the condylar flare has given some of the most satisfactory femoral stumps. Six patients had this type of amputation. They required a good deal of postoperative care to insure even coverage of the stump. In our experience heavy muscle flaps give poor stumps on which to fasten a prosthesis, but we feel that this operation is at present the most desirable one we have for amputations in the neighborhood of the knee joint. At the operation, gas oxygen and cyclopropane are considered the ideal anesthetics for amputation, although at times spinal anesthesia in the aged patient is particularly satisfactory.

CAUSES FOR REAMPUTATION

While amputation proximal to the metatarsals may occasionally be employed, we feel that it is generally unsatisfactory both for the application of an efficient prosthesis and for weight bearing. Reamputation with a tibial stump of 7 inches would usually be more satisfactory. If for some reason the tibial stump is less than 5 inches, we feel that the result will be much better if the fibula is excised at the time of the original amputation. Six reamputations were done because of a long or painful fibula. Figure 2 shows a pointed fibula the same length as the tibia. It was also freely movable and bothered the patient a good deal, so that excision was necessary. However, cross union between the tibia and fibula may give an excellent stump, as shown in figure 3.

Fig. 3.—Cross union between the tibia and fibula; an excellent stump.

because the wide condylar flare made the application of a prosthesis difficult. However, we believe that the fault does not lie with the type of stump. The prosthesis shown in figure 1 gave one of our patients a very satisfactory extremity. The socket is made of molded leather and is end bearing. The knees are at the same level and the femur does not protrude. The distal end of the femur with cartilage intact is a normal weight bearing surface and to leave it should be preferable to severance of the bone. But the stump is usually fitted with a conical wooden socket which is very unsatisfactory and frequently painful. In our experience the Gritti-Stokes amputation usually gives a painful and unsatisfactory stump. In the thigh it is advisable to preserve as long a stump as possible above the condylar flare. The shortest stump in this series was 4 inches. This is regarded as undesirable but a great deal better than a disarticulation at the hip joint for the wearing of a prosthesis. It was also noted that the longer the stump the more satisfactory the gait of the patient, for the amputation stump could fit more securely within the prosthesis and be a more active lever in walking.

There were in this series sixteen cases in which amputation was done because of a primary malignant tumor of the bone, and it might be mentioned at this time that we are beginning to feel that, when the tumor involves either the humerus or the femur, disarticulation at the proximal joint offers the best opportunity for survival, even though it greatly increases the difficulty of fitting the patient with a prosthesis. So far, more of the patients in our series are alive after disarticulation at the proximal joint than after severance of the affected bone. In several cases, sections of the marrow at the originally selected amputation site yielded tumor cells, so that amputation at a higher level was necessary.

Fig. 4.—Reamputation and epiphyseal fusion were necessary because of growth of the bone. Note the open epiphyses.

Five patients were reoperated on for removal of painful spurs, and many more had tender points over spurs which, while not enough to warrant reoperation, were annoying. We therefore feel that great care should be exercised in exposing and retracting the periosteum at the operation. Seventeen patients in this series without alcohol injections of the nerves had no complaints, but

3. Callander, C. L.: A New Amputation in the Lower Third of the Thigh, J. A. M. A. 105:1746 (Nov. 30) 1935.

DR. RICHARD G. PACKARD, Denver: The indications for amputation are comparatively few: much fewer, than some three decades ago. Many bad compound fractures with loss of bone substance can now often be successfully handled with skeletal traction until healing takes place instead of being at once condemned to amputation. The use of insulin and the interdiction of tobacco have kept untold numbers of patients with diabetic gangrene and with thrombo-angiitis obliterans from the surgeon's knife, and the x-rays have cured many cases of gas bacillus infection. But there are the definite indications: complete severance of the main blood supply, uncontrollable hemorrhage, extensive cancer, deformity with painful weight bearing, persistent nonunion, gangrene of the extremity and overwhelming infection. A definite contraindication to immediate amputation is shock. The site of election is paramount. In the foot one should not amputate above a point distal to the bases of the metatarsal bones because of almost inevitable muscle imbalance causing a bad equinus. Pirogoff's method, by which weight can be borne on the posterior portion of the os calcis, implanted into the under surface of the tibia, or Syme's, in which the whole weight is borne on the sawed end of the tibia, is of distinct advantage to the patient who cannot afford a prosthesis. The lower third of the leg should not be chosen on account of the relatively poor blood supply. The site of election in the leg is 7 inches below the insertion of the hamstrings, with the fibula divided 1 inch higher than the tibia. Here the anterior or anterolateral flap should predominate, the bone end cleared of periosteum three-fourths inch above its tip, rounded over and covered with a muscle flap, and a splint used to combat flexion of the knee. If less stump is necessary, it must be at least 1½ inches long and all of the fibula removed. Disarticulation

at the knee is not recommended. I have been reviewing the closed method of amputation. But sometimes when time is a big factor, infection is overwhelming and much crushing has occurred or immediate transportation is necessary, I resort to the open or guillotine method, which allows full exposure for dressing. There is the flap or the flapless type, the latter the choice. Further surgery is always necessary. Meanwhile skin traction is essential to prevent retraction of soft tissues and to limit spread of infection. Secondary operation must be done after treatment with diluted solution of sodium hypochlorite and is sometimes possible after ten days. In all these cases persistent skin traction is very valuable in preserving as long a stump as possible.

DR. JAMES R. ELLIOTT, Kansas City, Mo.: I had a rather unusual opportunity of observing end results in amputation through thirteen years' connection as consultant orthopedic surgeon in the United States Veterans' Bureau. Those men were receiving disability payments of from 45 to 65 per cent and when they were not able to wear their artificial limbs they received 100 per cent disability, so that there was some inducement for them to be disabled. I observed that the Gritti-Stokes type of amputation lost less time from furuncles of the stump than any other amputation. If a muscle-controlled knee can be preserved satisfactorily it should be by all means, but if that is not possible the Gritti-Stokes type of operation is by far the procedure of choice so far as loss of time of the patient from furuncles on his stump is concerned.

DR. RALPH K. GHORMLEY, Rochester, Minn.: In spite of the advances made in conservative treatment of vascular disease, we still have a real problem in trying to save some of these limbs and also in saving most of the limb if we can when amputation is inevitable. When these people come to amputation they have been through a long period of conservative treatment, they have failed, and they have often lost their morale and their means and everything that goes to make for a good result. The first important thing in considering these cases when both limbs still remain with one gangrenous is to try to get the best possible stump and, of course, that is one below the knee, because almost inevitably sooner or later they will come to amputation of the other leg and probably a little later it will have to be done above the knee. The only way that one can reliably—and that is not too reliably—decide where to amputate is to make an incision below the knee joint without a tourniquet and see what exists in the way of collateral circulation. The main vessels will probably be occluded in most instances. In using that test I have been able in many instances to get a satisfactory stump below the knee, which is a big help and saves much in the way of trouble later on. The authors have described the proper method of treating the bone. I should like to stress the handling of the soft tissue. Everything that one reads on amputations below the knee tells one to use the long anterior flap. Now, in these cases, particularly of Buerger's disease or diabetes, in which one is occasionally able to amputate below the knee, if either flap is going to break down it is the anterior flap. The only satisfactory way is to make a long posterior flap. Make the flap long and from the flap excise most of the muscle tissue. Do not leave a bulky mass of muscle over the end of the bone and hope to have it heal, because that muscle is going to slough; while it may be absorbed, more often it will slough and break down. Peel off practically all the muscle tissue and leave a very thin layer of muscle and fascia to cover the end of the bone. Then fix the flap in place with sutures to the soft tissues along the anterior surface of the bone and close with a drain practically always, because they are almost always infected and potentially serious from that standpoint. I use a prophylactic dose of gas gangrene antitetanic antitoxin because a flare-up of that type of infection may occur in the stump.

DR. J. ALBERT KEY, St. Louis: I am sorry Dr. Evans of Minneapolis is not here, because he has just completed a study of several hundred amputations. His idea was to find what type of amputation stump gave the best results from the standpoint of the ability of the patients to wear their prosthesis and also from the standpoint of their reentering the hospital later for further operation. He concluded that all amputations of the lower extremity should be done at or above the knee; in

other words, an end bearing stump through the condyles gives a much more satisfactory result than any amputation through any portion of the leg or the foot if it is necessary to remove the metatarsals. This is something we should be thinking about, because, as we analyze our results, we may come to agree with him. I should like to emphasize that in malignant conditions we should not compromise. We should not attempt to save an inch or two of bone but should disarticulate.

DR. LENOX D. BAKER, Durham, N. C.: There is one amputation, Pirogoff's, that Dr. Packard mentioned, which has not been done extensively in this country. A few years ago Dr. Harris of Toronto reported a series of low amputations with weight bearing stumps at the heel that were very satisfactory. In North Carolina, an agricultural district, the idea of fitting a farm worker with a prosthesis is out of the question; the limbs do not wear well because of the grit and dirt, and as a result I have resorted, when possible, to Pirogoff's amputation with very satisfactory weight bearing limbs. The patients are able to get around the house without putting on a prosthesis and they are able to work as agricultural laborers.

DR. ROBERT D. SCHROCK, Omaha: In the discussion there has been omitted what to me seems a very important feature in the immediate postoperative treatment of these amputation stumps, as a preventive measure to the shortening of the muscular flap, to prevent undue strain on the skin, and that is the use of mole skin adhesive skin traction. It will add to the comfort of the patient. There will be less disturbance of healing and there will be less involvement of the nerve ends.

DR. S. PERRY ROGERS, Chicago: I am gratified to note the favorable mention of disarticulation of the knee. Amputation through the knee joint, disarticulation, exarticulation or amputation in contiguity does not deserve the neglect and disrepute into which it has fallen. The fundamental principles here are very simple. The functions of the lower extremity are weight bearing and locomotion. End bearing is physiologic; side bearing is unphysiologic, inefficient and painful. The condyles plus the patella can provide a firm horizontal surface of 20 square inches, much larger than the end surface in the Gritti-Stokes or Callander operations, an obvious advantage because pressure per square inch is inversely proportional to surface area. The power of locomotion can be preserved and muscular atrophy prevented only by attaching all muscles and tendons to the end of the stump. Some disarticulation stumps have been unsatisfactory for one of two reasons. The patella has been tender because it has ridden loosely and freely on the front of the femur. The patella will fuse to the femur if its tendon is simply anchored; by dovetailing or pegging it can be fixed low enough to contribute to the end bearing surface area. Other stumps have undergone gradual atrophy and ulceration of their terminal integuments and even protrusion of the bone. If all tendons are attached to the end of the stump, however, neither of these complications will occur even after amputation at a very early age. I have recently described an original operation embracing three essential points: formation of a large anterior flap including skin, fascia, synovium and patellar ligament in one piece, fixation of the patella in the anterior intercondylar groove with its lower hole level with the lower surfaces of the condyles, and suture of the patellar tendon to the hamstring tendons in the posterior intercondylar notch. This operation is called a physiologic amputation, because it distributes the body weight over the largest surface area available for end bearing, because it utilizes bony surfaces accustomed to weight bearing, and covers them with the amount and kind of soft tissues which bear weight elsewhere in the body, because it preserves the function of all tissues left in the stump, because it allows continued growth of the stump without atrophy of its integuments, and because it adapts itself to a prosthesis which resembles a normal leg and which is worn as a shoe is worn on the foot.

DR. FREDERICK H. VOM SAAL, Oklahoma City: I am amazed at what Dr. Key says. We have many good tibial amputations and the patients are well satisfied with them, and our experience, if anything, is just the opposite. We think that any length of the tibia down to an inch and a half, which is very short, is preferable to an operation at or above the knee.

THE INHERITANCE OF EPILEPSY AS
REVEALED BY THE ELECTRO-
ENCEPHALOGRAPH

W. G. LENNOX, M.D.

ERNA L. GIBBS

AND

F. A. GIBBS, M.D.

BOSTON

Though the opinion that heredity is an important influence in epilepsy is widespread, only one epileptic person in five is able to name any relative who has been similarly affected. Like an underground stream, the predisposition to seizures can flow unrevealed and unsuspected through numerous generations and then suddenly, assisted perhaps by some injury to the brain, appear in a certain individual as epilepsy. This predisposition, carried as it is in abnormal genes, has never been demonstrated in the clinical laboratory.

There are reasons for believing that a study of cortical electrical activity might clarify the problem of inheritance in epilepsy. This cortical rhythm, as recorded by the electro-encephalograph, is a fundamental constitutional characteristic. Evidence of this is the individuality of each person's electro-encephalogram and, what is even more convincing, the similarity of the electro-encephalograms of similar twins.¹ This similarity is observed both in twins with normal and in those with abnormal records. Epilepsy is a paroxysmal cerebral dysrhythmia.² Our studies have shown that rhythms of abnormal frequency are present not only during seizures but usually also in the intervals between.³ Furthermore, an abnormal rhythm has been observed prior to a patient's first seizure. If dysrhythmia is a constitutional characteristic, it should be demonstrable in persons who have no epilepsy but only the predisposition. Although the frequency of the electrical waves of the brain varies with changing activity of the brain, an inheritable disorder which was present in the parent before the conception of the child should persist throughout life. Obviously, the most likely persons to examine for constitutional disorders are the nonepileptic near relatives of the epileptic. We began to study this group two years ago.

The present report deals only with records obtained by means of an ink-writing oscillograph. The more precise evidence from electrically analyzed records will be reported later. Patients were those coming privately to us or our colleagues or else attending the Neurological Service of the Boston City Hospital. They were unselected, and no attempt was made to eliminate so-called symptomatic epileptic persons, for a statistical study by one of us has shown that the symptomatic epileptic, in whom brain defect or injury antedated the first seizure, have three times more near relatives with seizures than the nonepileptic.⁴ Simultaneous records

were made over six cortical areas, since an abnormality of rhythm may be limited to one area. Records were run for at least twenty minutes and a short period of overventilation was used as a means of emphasizing abnormal patterns. Such induced abnormalities were not counted, however, unless they were the diagnostic wave and spike pattern of petit mal. The decision as to abnormality was made by one of us (E. L. G.) after inspection of the whole record. Abnormalities consisted of waves or series of waves which were abnormal in rate, with frequencies below nine per second or above twelve per second. Examination of some subjects was repeated without altering results. For comparison, electro-encephalograms were made of fifty healthy persons, mainly professional and other workers on the staff of the Neurological Unit who did not have a family history of epilepsy.

RESULTS

Records were made of 138 persons, of whom 100 were parents and twenty were siblings or children of seventy-six patients who had cerebral dysrhythmia and

PETIT MAL PATIENT, PARENTS AND TWIN SISTERS

Portions of the electro-encephalographic records of a patient with petit mal epilepsy and (from top to bottom) his mother, father and younger identical twin sisters. Only leads from the right motor and occipital regions are shown. Of the patient's record the right hand portion was made during a petit mal attack, the left hand portion during a subclinical seizure. The mother's record is wholly normal. The father and two daughters have abnormally slow waves, predominantly in the motor area. The line at the bottom marks seconds, and at the right is the signal made by 50 millivolts.

the clinical diagnosis of epilepsy. Of these 138 persons, 54 per cent had definite dysrhythmia (males 52 per cent and females 57 per cent). Eleven per cent had doubtful dysrhythmia. When both parents were tested, 60 per cent of these individual records were abnormal; when one of the parents was tested, only 31 per cent were abnormal. Presumably the normal parent was more willing or more available for the test. Of the control group, 6 per cent had definite and 12 per cent had doubtful dysrhythmia. Therefore, definitely abnormal records were nine times more frequent among those closely related to an epileptic patient than among those not related.

In forty-six instances, records were obtained of both parents of the patient. In 28 per cent of these families the records of both parents were definitely abnormal. In 94 per cent the record of at least one of the parents was unmistakably abnormal. In 4 per cent

the record of one parent was normal and of the other doubtful. In only one instance (2 per cent) was the record of both parents normal.

Samples of the records obtained in one family appear in the accompanying tracing. In this family a son, the patient, had petit mal epilepsy. The mother's record was entirely normal. The father's record showed periods of abnormally slow waves over the motor areas of the cortex. Two 10 year old sisters, who were identical twins, had records which were similar. Both, like the father, had abnormally slow waves principally over the motor areas. The only history of neuropsychiatric disorder in the family was a sister of the father, who was in a mental hospital.

For the most part, abnormalities were in the direction of slow, three to seven per second waves, many of square configuration. These square topped waves were often inverted. Abnormalities were most conspicuous over the motor areas. In only three instances was the diagnostic wave and spike formation of petit mal present, and one of these parents had had petit mal in childhood. The degree of abnormality varied. Occasionally a normal parent had a worse looking record than his epileptic child. Dysrhythmias of the type encountered in these parents are not found exclusively in patients with epilepsy but occur in many children with severe behavior disorders, in many schizophrenic patients and doubtless in other conditions as yet unexplored. Three of the 118 parents studied had had seizures in childhood. Some of the parents might be called "neurotic" or unduly apprehensive. However, we emphasize that rhythms which were grossly abnormal occurred in some of the most intelligent and emotionally stable of the relatives. Dysrhythmias may or may not be associated with symptoms of nervous disorder. The existence of gross cortical dysrhythmia in 6 per cent of our normal control group and of waves of questionable normality in another 12 per cent is not surprising. Persons with a "predisposition" to disease outnumber by many times those who actually have disease. Looking forward from this control group, we do not know what clinical disease those showing dysrhythmia (or their descendants) may be subject to. Looking back from our epileptic patients, we believe that dysrhythmias in parents must be associated with the epilepsy of their children. Among our near relatives of epileptic patients, approximately 2.5 per cent have, or have had, epilepsy, and approximately 50 per cent have definite cortical dysrhythmia. Therefore in this small group those with a predisposition to epilepsy outnumber the epileptic twenty to one.

The present study demonstrates that, even when a patient gives no history of epilepsy in his ascendants, one or both of his parents may have a cortical dysrhythmia. The conclusion seems inescapable that the cerebral dysrhythmia associated with epilepsy is inheritable and the parent of an epileptic patient who shows such cortical dysrhythmia is a carrier of the disorder. Epilepsy has long been recognized as a recessive mendelian trait. Our study suggests the possibility that cortical dysrhythmia, the essential manifestation of epilepsy, may be a dominant trait. Since epileptic persons form about 0.5 per cent of the population, those predisposed to epilepsy or a kindred disorder would number about 10 per cent. A mating of two predisposed persons by the laws of chance would occur only once in a hundred matings. Yet definite cortical dysrhythmia of both parents occurred in 28 per cent of our families. If an epileptic person marries, he should choose a person

with normal brain waves. Marriage is safer for such a pair than for two persons whose personal and family histories are free of seizures but who both have cortical dysrhythmia.

CONCLUSIONS

Electro-encephalographic tracings were made simultaneously over six areas of the cortex in 138 parents, children or siblings of patients with epilepsy. Definitely abnormal records were obtained in 54 per cent of the relatives, against 6 per cent in a control group who were unrelated to epileptic persons. In forty-six of the families, records were made of both parents. In 28 per cent both parents and in 94 per cent at least one parent had abnormal records. We believe this evidence indicates that the dysrhythmia of epilepsy is inheritable and that such a dysrhythmia when demonstrable may represent a predisposition to epilepsy or some allied disorder.

These observations should be of practical value in the prophylaxis and eugenics of epilepsy and should assist the physician in tracing the descent of epilepsy and in advising patients and their relatives about marriage.

ABNORMAL MOVEMENTS FOLLOWING INJURY TO THE FACIAL NERVE

EDMUND P. FOWLER JR., M.D.

NEW YORK

Abnormal movements of the face following recovery from toxic neuritis of the facial nerve (Bell's palsy) are much more common than is generally supposed. Patients who recover from traumatic lesions to the nerve invariably show abnormal associated movements of the facial musculature and often have annoying tics on the affected side of the face.¹ Some patients, after the disappearance of the paralysis, suffer from sweating and excessive lacrimation on the injured side while eating (crocodile tear syndrome²).

Opinions as to the cause of these phenomena have been divergent. One school maintained that the ticlike movements are central in origin and the other that they are peripheral. Unfortunately, the two most assiduous workers in this field, the late Dr. Arthur B. Duel and the late Sir Charles Ballance, while studying facial nerve grafts disagreed as to the origin of the ticlike movements and, on different sides of the ocean, continued their experiments on the same material and published results without close collaboration. It was my privilege to work in the laboratory of the late Dr. Duel while certain crucial experiments as to the cause of this so-called facial tic were being conducted and to examine the material of the late Sir Charles Ballance as well. It is my purpose in this paper to report these experiments and to clarify the situation with regard to the divergent opinions.

Those who have read all the papers of Duel and Ballance will find that even in the early papers³ both these workers were much concerned over the occurrence of a severe myoclonic spasm in the faces of all the

monkeys in which the nerve had been cut experimentally so that a graft from some other nerve in the body could be inserted. Ballance was convinced that the movements were central in origin, and to prove his theory the rolandic motor facial cortex of several monkeys was removed for microscopic study before the autopsy. These specimens were taken to England by Ballance and were the basis of a paper.⁴ He reported that there

observation was given by Dr. Abner Wolfe of the Department of Neuropathology at Columbia University. Since these results were in complete disagreement with those of Ballance, Dr. Duel obtained from him the actual specimens from which his observations had been made. Dr. Wolfe and I examined these specimens and were not able to agree with Ballance as to the changes observed by him. Examination of the facial nuclei in the medullas of "ticking" monkeys also showed no abnormalities.

The Nissl reaction is notoriously difficult to interpret, and in our opinion the changes reported by Ballance are simply normal variations due to microscopic technic and inherent in the method, particularly when small specimens are used.

The ticlike movements seemed to be associated with the continued blinking of the eyes which is so characteristic of an excited monkey. It has been suggested that the true cause of the facial ticlike movements might be the fact that when the nerve repaired itself, single axons or entire nerve bundles became misdirected.⁵ When they grew down they did not enter the sheaths which they had previously occupied, and therefore individual muscles would be enervated by cells in the medulla which had previously enervated other muscles. The resulting confusion might easily cause the associated movements and the ticlike movements as well. To prove this point, the skin was dissected forward on one side of the face of a series of normal monkeys and the peripheral branches of the facial nerve were isolated as they passed forward over the anterior border of the parotid gland. Mild faradic stimulation being used, a large branch which enervated the eye and another which enervated the lower lip were selected. When each was freed for a considerable distance and cut, the proximal trunk which had previously enervated the eye muscles was sutured to the distal portion of the branch that had previously enervated the lip muscles and, likewise, the proximal portion of the nerve that had

Fig. 1.—How the nerve trunks to the eye were switched to the lip and the branch previously enervating the lip was switched to the eye. Reeducation occurred with healing of the paralysis. There were no ticlike movements.

was a change in the pyramidal cells of the facial area of the motor rolandic cortex of the left side of all monkeys which had had a unilateral facial nerve graft on the right (that is, those monkeys which had an external traumatic lesion of the facial nerve). The conclusions were based on a comparison of the Nissl reaction of the pyramidal cells in specimens removed from the two sides. These experiments were continued by Duel after Ballance's return to England, with this difference: Monkeys were allowed to recover after the removal of the facial area in the rolandic cortex on the side opposite the peripheral lesion. The ticlike movements of the face were found to persist without change.

To make sure that the result was not due to incomplete ablation of the rolandic cortex, in two monkeys the entire rolandic motor area on the side opposite the peripheral lesion was removed, and in four monkeys the entire cerebral hemisphere was removed on this side; no change took place in the ticlike movements. In two monkeys, when the cerebral cortex was removed from both sides it was difficult to elicit the facial tic because of the condition of the monkey, but associated movements (which, with conjunctival irritation, invariably accompany the ticlike movements) were persistent on the side where the facial nerve had been cut and repaired. They were not present on the normal side.

The pyramidal cells of the motor cortex in these monkeys were stained by the Nissl method. The facial area was delineated with a faradic current and marked with silk threads before the removal of the specimen and the death of the animal, so that it could be compared with nearby areas as well as with the opposite side. No variation in the Nissl reaction of the pyramidal cells of either side was noted. Confirmation of this

Fig. 2.—How the nerve to the eye was switched to the lip. With healing, spasmodic movements of the lip occurred which were synchronous with blinking of the normal eye on the other side of the face.

previously enervated the lip was sutured to the distal portion of the nerve which enervated the eye (fig. 1). The skin was then replaced and the monkey allowed to recover. For the first few days there were a partial inability to close the eye on the side which had been operated on and an obvious deformity of the lower

lip, but, with reinnervation of the distal stumps, both deformities decreased steadily until, in a completely recovered monkey, there was no evidence of the paralysis and, what is more important, no associated movements or ticlike movements.

In two monkeys in which the enervation to the eye was attached only to the distal stump of the nerve to the lip, the orbicularis palpebrarum remained partially

Fig. 3.—How a single axon can enervate several parts of the face and be responsible for abnormal associated movements.

paralyzed for months, while the movement of the lip returned in ten days (fig. 2). In these monkeys, blinking of the normal eye was associated with a movement of the lip on the side which had been operated on, and if the monkey was extremely excited or the conjunctiva on either side was irritated by a foreign body the twitching of the lip resembled the ticlike movements produced by cutting the main trunk of the facial nerve. Once established, this "blinking" of the lip remained constant (all the animals were observed for more than eight months).

In doing both these operations it was necessary to sacrifice a few small nerve tendrils in order to move the trunks from one part of the face to another. Apparently, neurofibrils from the proximal end of the cut nerve stumps grew across the intervening spaces, or possibly, but less likely, there was enervation of the paralyzed muscle bundles by new twigs from unparalyzed nerve trunks. In three months there was considerable recovery of the paralyzed eye on the side which had been operated on in the monkeys receiving no new enervation of the eye. After four months the eye could be completely closed. The distance from the loose proximal stumps to the external canthus of the eye in these monkeys was approximately 3.5 cm.

At this time Dr. Duel discovered that all his patients who had recovered with facial nerve grafts had the associated movements which were so apparent in the experimental animals. Some of the patients had annoying ticlike movements as well. Staring fixedly at them often made their faces twitch. Those with mobile faces, the unstable, excitable persons, were much more likely to twitch than the more stolid persons with "dead pan" faces. It was extremely difficult with human beings to be sure that the involuntary twitching of the entire face was associated with blinking of the eyes. The reason for this uncertainty is that the involuntary blinking of the human eye is often so rapid as to be indiscernible when the attention is fixed on a bizarre twitching of another portion of the face.

In this connection, the observation was made that traumatic lesions of the facial nerve in cats produced no tic which was comparable to that found in monkeys

and occasionally in human beings. There was a peculiar excessive vibration of the whiskers while the paralysis lasted, but this in no way resembled the tic seen in monkeys and human beings. Its cause was not determined. Irritation of the conjunctiva in cats, when facial palsy healed, produced associated movements of all the muscles on the side which had been operated on, with much less movement of the whiskers on the normal side. When it was established that the ticlike movements were commonly associated with voluntary or involuntary blinking of the eyes in monkeys and human beings, the absence of this phenomenon in cats was explained by the fact that they rarely blink their eyes. When they do so, the movement is very deliberate and the associated movement is likewise very slow, so that both are much less apparent than in monkeys and human beings. Cats express their emotions more by arching the back and moving the tail than by facial expression.

During this stage in the search for the cause of facial tic, Duel performed a second operation and graft on two of his patients who had severe and annoying facial tic. When recovery from the facial paralysis occurred the second time, the tic was exactly as bad as it had been after the first repair.

At this point, Prof. Lewis Weed of the Department of Anatomy at Johns Hopkins University School of Medicine sent Howard A. Howe and Sarah S. Tower to the Laurelwood laboratories to study the problem. These workers suggested that the facial tic might be due to a splitting of the individual axons at the point of trauma and the enervation of several parts of the face by neurofibrils from a single axon. (A comparison of observations on the sciatic nerve of rabbits⁶ is of interest.)

A series of experiments were then conducted on monkeys which had previously been subject to sufficient trauma of the facial nerve so that, with recovery, the

Fig. 4.—The Howe-Tower experiment. After repair at AB and cutting of the branch at CD, stimulation at D with faradic current produced movement of the lips and nose. Stimulation at C produced movement of the entire face including the ears and the platysma and frontalis muscles. On the normal side, with no lesion at AB, stimulation at C produced no reaction whatever.

typical associated movements and spasms were apparent. The skin was reflected over the parotid gland on both sides, and several peripheral branches of the facial nerve were isolated. The most typical trunks (fig. 3) were chosen. One of these branches was cut, and its counterpart on the normal side was also cut. The

6. Langley, J. N., and Anderson, H. K.: The Union of Different Kinds of Nerve Fibers, *J. Physiol.* 31: 365, 1904.

distal stump (at *D*) was then stimulated with a mild faradic current and found to enervate a nearby, highly localized region on both sides. Stimulation of the proximal stump on the side which had been operated on, however, invariably produced movement of the entire face, scalp and platysma, while stimulation of

Fig. 5.—Traumatic neuroma in the facial nerve of a monkey.

the proximal stump on the normal side produced no movement whatever. These experiments have been reported in detail by Howe, Tower and Duel⁷ and explain the true origin of the ticlike movements.

The stimulation of the proximal end of a cut peripheral branch which moves the entire face, even if the facial nerve has been severed in the internal auditory meatus, shows that on the injured and repaired side there is always enervation of several parts of the face by a single axon. Sections through the neuroma which is invariably present at the site of repair confirm the belief that this axon reflex is produced by a splitting of the neurofibrils at the point of repair. The individual axon passes into the neuroma and breaks up into neurofibrils which run in every direction (fig. 4), and those neurofibrils which happen to encounter peripheral branches of the severed facial nerve enter different branches. Thus a single axon may send out neurofibrils, of which some get lost in the fibrous tissue of the neuroma and others may reinnervate distal branches which belong to the neck, lip, nose, eye or forehead or, conceivably, all these regions. That is, if any type of stimulus reaches the medullary cell belonging to this axon, it produces movement of several of the muscles of the face.

From the foregoing discussion it is apparent why the monkeys move the entire face on the affected side

when they blink their eyes or even when they move the alae of their noses with fast respiration (Howe) and why human beings have ticlike movements of the face not only with blinking of the eyes but also with the more static function of trying to keep the face immobile.

I have seen one patient who had recovered from Bell's palsy in whom the new axons grew across the midline and produced twitching of the alae of the nose and parts of the lower lip and chin on the normal side coincidentally with any movements of the formerly paralyzed side of the face. There were also, of course, marked associated movements on this side.

It is obvious that inserting a new graft when there is an annoying facial tic will not produce reduction of the tic. It is practically impossible to believe that when the second set of neurofibrils grows down they will redistribute themselves any better than did the first set. Indeed, one might expect even a worse result.

If the typical ticlike twitching of the face is present, one may presume that there has been a peripheral lesion of the facial nerve and that repair has taken place. In this connection, the following case is of interest:

B. W., a Negro woman aged 45, a Christian scientist, presented herself at the Vanderbilt Clinic with a large subperiosteal abscess involving the whole mastoid, zygomatic and temporal region on the right side and a history of discharge from the ear on the right side of nine weeks' duration. A roentgenogram of the mastoid showed evidence of mastoiditis and cortical perforation on this side. In addition, the patient had paralysis of three weeks' duration on the left side of the face, which was much more apparent in the lower part than in her forehead. Since the disease had been neglected and the cortical perforation was present externally, it was suspected that she might have an epidural abscess involving the Rolandic motor cortex on the right side. This theory was enhanced by the fact that when faradic stimulation was present on the left side no reaction of degeneration was apparent and the paralysis was confined to the lower portion of the face. However, the patient was extremely ill, and after evacuation of the subperiosteal abscess, which involved most of the right side of her skull, and the removal of the infected air cells of a very large mastoid cavity on this side, her condition was so extreme that it was deemed unwise to explore the epidural spaces, especially when no obvious break in the inner tables of the mastoid was apparent. The patient recovered quite rapidly after the operation and her facial

Fig. 6.—Branching axons from the neuroma shown in figure 5.

paralysis began to improve. She was loath to allow any further intervention. In fact, it was with great difficulty that she was persuaded to return occasionally to the clinic for dressings. I saw her about six months after the operation, and at this time her facial paralysis on the left was entirely healed except for the characteristic ticlike movements which are invariably present after peripheral traumatic lesions of the facial nerve.

The appearance of the tic in this case indicated that the facial paralysis was produced by toxic neuritis

7. Howe, H. A.; Tower, Sarah S., and Duel, A. B.: Facial Tic in Relation to Injury of Facial Nerve: Experimental Study, *Arch. Neurol. & Psychiat.* 38: 1190 (Dec.) 1937.

(Bell's palsy) of the left side rather than by an infection of the rolandic motor cortex of the right side.

Unfortunately, experiments to ascertain the cause of facial tic and associated movements have resulted in an explanation which shows that when established they cannot be cured by any known technical method. On

Fig. 7.—Facial palsy following operative removal of a cholesteatoma which surrounded the facial nerve at the knee of its descending portion on the right.

the other hand, they can be minimized. If the facial nerve is exposed in a mastoid operation, it should be carefully avoided. If paralysis is present and a graft necessary, any uncut vestige of the nerve should be kept. The graft can be placed over this vestige, especially in cases of recent involvement. In cases of old involvement the neuroma should be shaved away from the nerve in an effort to save deeper lying portions of the nerve which may still be normal. This nerve should not be cut off sharply above and below the lesion, as advocated by Duel.³

The facial twitching can often be controlled after it develops. Patients who are annoyed by it must be trained to reduce their facial expressions. They can teach themselves not to blink so much. They can teach themselves to relax their faces to the "dead pan" type. Making or maintaining a so-called poker face requires definite muscular effort. Any movement, whether voluntary or involuntary, is likely to produce the very annoying twitch which they are trying to avoid. They should therefore train themselves in front of the mirror to smile out of the paralyzed side of the mouth. If they can achieve an even smile, it is a triumph. They should try every means to avoid being self conscious when some one is looking directly at them. Occasionally it is necessary to avoid direct gaze.

It has been found that some patients are much benefited by keeping a pipe or a cigaret holder in the paralyzed corner of the mouth. This reduces whatever deformity may be present and therefore the embarrass-

ment of the patient. The less self conscious the patient becomes, the less his face moves. For this reason, if there is still a considerable deformity a year or two after a successful graft or decompression, a plastic operation should be used to straighten the face. Galvanic stimulation is a help to keep the muscles of the face exercised while they are not enervated. However, this may be overdone. As soon as reinnervation takes place, it is wise to confine the galvanic exercises to those portions of the face which are not yet enervated. Sometimes the abnormal side has a tendency to be overactive because of the short circuited enervation, and this may well be exaggerated by excessive use of galvanic stimulation.

The etiology of the abnormal movements suggests that every effort should be made to relieve facial paralysis at the earliest possible moment. Thus the pressure of infection from otitic involvement of the nerve should be relieved at once by supplying adequate drainage. If the paralysis does not begin to disappear a few days after operation on the mastoid, decompression of the fallopian canal is indicated.

If directly after operation on the mastoid there is facial paralysis, the wound should be explored at once and the point of trauma found. Often this is simply a spicule of bone which has penetrated the sheath and permitted entrance of infection. If it is not, decompression of the nerve or a graft will be needed anyway, so no harm is done by operating. Decompression of the nerve has been shown to produce prompt alleviation of recurrent Bell's palsy, and therefore there is less

Fig. 8.—The patient shown in figure 7 two years after decompression of the injured part of the nerve on the right. Note the associated movement of the entire right side of the face, including the platysma.

chance for the abnormal movements to develop. Lastly, if faradic response disappears, and especially if reaction of degeneration can be demonstrated, decompression should seriously be considered for ordinary Bell's palsy, particularly the recurrent type. The fewer axons which degenerate, the fewer new axons there will be to break up and cause multiple enervation of the face.

CONCLUSIONS

1. Associated movements of various parts of the face occur after recovery with all severe injuries to the facial nerve.

2. Ticlike movements occur in patients with healed facial palsy of traumatic origin if they blink their eyes a great deal or have mobile faces.

3. The associated movements and facial spasms occasionally follow facial paralysis of toxic origin.

4. Both of these phenomena are caused by splitting of axons in the neuroma which invariably forms at a point of severe injury, whether toxic or traumatic. There is consequent enervation of several parts of the face by neurofibrils from a single axon.

5. These phenomena are not caused by improper rerouting of nerve bundles because, when this is done experimentally, reeducation takes place so that no associated movement or ticlike movement occurs.

6. These phenomena are not central in origin.

7. The ticlike movements are pathognomonic of a peripheral nerve injury, and if they occur one can be sure that there has been trauma or severe toxic disturbance of the trunk of the nerve.

8. Every effort should be made to relieve peripheral nerve palsy as early as possible so as to forestall serious damage to the nerve and subsequent production of abnormal movements.

630 West 168th Street.

ABSTRACT OF DISCUSSION

DR. JOSEPH A. SULLIVAN, Toronto: I have been carrying on investigations in monkeys, and with information I have gained therefrom and deductions made from observations in practical experience in operating on 100 human beings with facial nerve palsies, and reinvestigating the histologic observations of Ballance, I cannot be as dogmatic as Dr. Fowler is in his conclusions. The author states "To make sure that the result was not due to incomplete ablation of the rolandic cortex, in four monkeys the entire cerebral hemisphere was removed on the side opposite the peripheral lesion without change taking place in the ticlike movements." Extirpation of the cerebral cortex does not necessarily mean that all the upper nuclei have been completely destroyed. From physiologic experiments we know that this is true, or its removal may have been so difficult that the medullary region has been injured. Dr. Fowler states in addition that "when the cerebral cortex was removed from both sides it was difficult to elicit the facial tic," owing to the condition of the monkey. I would appreciate it if he would explain this to me. I should like to know why he says that no variation in the Nissl reaction of the pyramidal cells of either side of the motor cortex was observed, closely following. The Nissl reaction is notoriously difficult to interpret. Were not all these monkeys operated on, immediately repaired or grafted? Had there been time for histologic changes to take place either in the pyramidal cells of the motor cortex or facial medullary nuclei. I do not think so, but there could be a physiologic disorder present, so ably propounded by Ballance and which I still adhere to. The isolation of the facial medullary nucleus is a most exacting procedure, and I cannot accept fully his statement that examination of the facial nuclei in the medulla of ticking monkeys showed no abnormalities; histologically may be so, physiologically no. I am in a position to demonstrate that the facial medullary nucleus does show a histologic change in a monkey whose facial nerve has been cut and allowed to undergo degeneration for varying periods of time before being repaired. I agree with Dr. Fowler that in fresh cases of facial nerve injury, if an uncut vestige of the nerve is present, this should be left and the graft placed alongside it. I do not agree, however, where in old cases a neuroma is present that it be shaved away without being completely excised. A neuroma means the presence of a marked neurofibrotic change in nerve tissue offering an impenetrable barrier to the downgrowth of neuro-

fibrils. It is not feasible to leave any part of it, as how can we tell macroscopically if the deeper portions of this tissue are normal? I never hesitate in sharply excising it well beyond its limits, ensuring an accurate coaptation of nerve to nerve and thereby applying a fundamental neurosurgical principle.

DR. ERNEST SACHS, St. Louis: I suspect that the author asked me to discuss his paper because of a piece of work that was done by a former assistant of mine, Dr. Malone, on the regeneration of nerves. Dr. Malone proved conclusively that in order to get a satisfactory regeneration of the nerve it is essential to excise a neuroma completely. He also demonstrated that when nerves are brought together as accurately as it is possible to do there is nevertheless rotation in the axis cylinders. Observations made twenty years ago by the Belgian Dustin in connection with studies on the regeneration of the fifth nerve proved that one couldn't make the axis cylinders hook up with the branch from which it had been originally separated. The explanation, that Dr. Fowler has brought forward explaining these particular movements by the splitting of the axis cylinders I am unable to express any opinion about. Dr. Malone didn't see any split axis cylinders, but the mere fact that we didn't see it doesn't mean that they do not occur. Neurosurgeons are deeply interested in the regeneration of the facial nerve, because in the operation on the eighth nerve tumors they are often obliged to divide the seventh nerve, and the problem of how to get the best regeneration comes up. One sees associated movements when one puts a hypoglossal nerve into the seventh nerve. When the patient recovers he frequently gets an associated movement; in fact, we want him to have it. That is, when he moves his tongue he contracts his face, but I have never seen anything like a tic movement. I agree that the origin of the tic is not cortical. Many years ago I worked with an intimate colleague of Sir Charles Ballance, Victor Horsley. They did not agree that the tic movements do not originate or resemble the movements that one gets when one stimulates the cortex, and I have never been able to accept the point of view that a true tic movement is anything other than of peripheral origin. Which part of the peripheral mechanism it occurs in, I am unable to say.

DR. EDMUND P. FOWLER JR., New York: In answer to Dr. Sullivan, all the monkeys here reported were late cases, that is, were monkeys that had had a facial graft one or two years or at least six months before. If a peripheral nerve is cut, there are no changes in the dorsal ganglions (the counterpart of the medullary facial nucleus) except at the beginning. One must furthermore cut the nerve close to the dorsal root ganglions in order to get changes. Similarly, one would have to cut the facial nerve close to the medulla and examine it early in order to get cloudy swelling and acute changes in the cells of the medullary facial nucleus. This I have not done. It was mentioned that the Nissl stain is difficult to interpret. I had the privilege of seeing Sir Charles Ballance's sections, and in my opinion the cells that he considered abnormal are histologic artefacts which are inherent in the difficulties of the method. With regard to the removal of the neuroma, it is quite true that in peripheral nerve surgery the best results are obtained by removing the entire neuroma. In facial nerve surgery I don't think this is so. After all, the most important thing in facial nerve surgery in the temporal bone is the decompression of the nerve. When the nerve is cut, especially by a bullet or an inept slice of a curet, the regenerating nerve has to hit a bull's eye; it has to hit an opening in the fallopian canal, which is very small. When we do facial nerve surgery, what we do is to take that bull's eye and make a trough. The graft acts only as a sluice-way for the new neurofibrils to grow down, and I don't think it makes enough difference if a little neuroma is left on top of what may be good, viable nerve fibers below. In answer to Dr. Sachs's question: Sir Charles Ballance's anastomosis monkeys had two kinds of associated movement. On irritation of the conjunctivas there was associated movement of the entire face as well as the associated movement of the tongue with hypoglossal anastomosis and lifting of the shoulder with accessory anastomosis. There was "winking" of the whole operated side of the face with conjunctival irritation of either eye. This I consider to be the same mechanism as the ticlike movements.

ANGIO-ENDOTHELIOMA OF BONE

J. FLETCHER LUTZ, M.D.

AND

LEWIS C. PUSCH, M.D.

YORK, PA.

Ewing¹ said in 1928:

The knowledge of endothelioma of bone has progressed slowly because of the difficulty of establishing its exact origin, and from the fact that many other tumors simulate the structure of endothelioma. Yet the new evidence accumulated during the past few years has considerably clarified this subject, while leaving several important questions still unsolved. One of the chief difficulties arises from the occurrence of metastatic tumors, chiefly from the kidney, which closely resemble certain primary tumors of bone, for which an endothelial origin seems practically certain. Metastatic adrenal tumors also present much the same structure, and the same difficulty. Yet it is now clear that there is a primary endothelioma of bone, with large clear cells and a marked tendency to angiomatous structure. . . . Another source of error, especially with tumors of large, clear cells, lies in the occurrence of liposarcoma of the bone-marrow, which produces a structure very nearly identical with that of some tumors generally classed as endothelioma. . . . It is now sufficiently attested that primary endothelioma of bone occurs in several subvarieties, in which the gross anatomy, structure, and clinical course are rather specific.

Ewing defined three structural varieties: (1) angio-endothelioma, which is solitary, cystic or telangiectatic; (2) multiple endothelioma, and (3) diffuse endothelioma, or endothelial myeloma (Ewing's tumor). It is the first of these three varieties, angio-endothelioma of bone, in which we are especially interested.

Kolodny² declared in 1926: "With the exception of a few, the most prominent pathologists hesitate to admit that angio-endothelioma of bone is an actual pathologic entity." The most outspoken among the pathologists, Ribbert³ said: "In no instance has it been proven that a so-called endothelioma originated from endothelium." The questions that suggest themselves to an unbiased investigator are "Is angio-endothelioma of bone a true pathologic entity? If so, what is the clinical incidence of this tumor?"

Codman⁴ stated of this very rare bone tumor that until 1925 not a single case had been recorded in the Registry of Bone Sarcoma of the American College of Surgeons. Kolodny⁵ found two cases of angio-endothelioma in the registry, which he himself had reported, one in 1924 and one in 1926. There are now seven angio-endotheliomas listed, one in the humerus, one in the tibia, two in the fibula, two in the femur and one multiple. However, perusal of the literature demonstrates that not all cases have been recorded in this registry. Ewing further stated that this tumor develops in the ends or shafts of the long bones, that it grows steadily, often perforating the shaft, invades the soft tissues and usually produces pulmonary metastases. The tumor may pulsate or yield a bruit and may be mistaken for bone aneurysm. It affects chiefly adults and elderly subjects.

Warner and Singleton⁶ in 1933 said: "Much confusion has existed regarding this tumor; its rarity and its resemblance microscopically to secondary adenocarcinoma frequently make diagnosis from sections difficult." A close resemblance to secondary bronchiogenic carcinoma in bone has been noted by Hirsch and Ryerson.⁷ . . . are seldom diagnosed clinically or . . . are radiosensitive and are not as apt to metastasize as are the other forms of endotheliomas or osteogenic sarcoma. When they do metastasize it is usually to the lungs.

Clinically, these tumors do not differ from any other form of sarcoma. They grow fairly rapidly and are painful and sensitive to the touch. They are generally solitary. There may be pulsation and a bruit.

Radiologically they are of bulky, cystlike formation, with fine lacelike trabeculae throughout. The wall is ill defined and has a tendency to blend with the soft tissues.

Fig. 1.—The lesion before amputation, showing its lacelike pattern.

There is marked destruction of bone without production of bone. The tumors resemble giant cell tumors, for which they have been mistaken radiologically. Giant cell tumors have specific radiographic signs which differ materially from those of angio-endotheliomas of bone. They are located mainly or exclusively in the epiphysis. They have a markedly widened shaft, preservation of the periosteal line and a sharp demarcation at the diaphysial border and are of multicystic appearance.

Brailsford⁸ in 1934 described this type of tumor as "hemangio-endothelioma of bone." According to him it produces a characteristic radiographic appearance. He stated that such neoplasms are relatively uncommon and are found in the bones of elderly patients, and that

the involved bones show a cystlike expansion with well defined septums. They have been seen in the long bones of the extremities and ribs and in the pelvis and vertebral column. He described a patient 60 years of age whose ninth left rib was involved. The growth had been diagnosed clinically as an aneurysm, owing to the presence of pulsation and bruit, which are sometimes present with that condition. Haswell Wilson reported that on microscopic examination the lesion was found to be a malignant hemangio-endothelioma. This is the only definite radiologic description in the various radiologic publications.

REPORT OF CASE

(Registry of Bone Sarcoma, No. 2156, American College of Surgeons)

History and Course.—A white woman aged 54, referred to one of us (J. F. L.) by Dr. Julius Comroe of York, Pa., Sept. 7, 1937, for an x-ray examination of the shoulder, traced the onset of symptoms to June 1936, when she was given a hypodermic injection for the relief of a supposed attack of coronary occlusion. The arm gradually began to swell at the site of the injection. Some time later a well defined mass was noted over the upper third of the arm. This mass continued to grow. The patient suffered continuously from pain in this region, which was aggravated by the least movement, and the region was exquisitely tender to the touch. Roentgenologic study revealed in the upper and outer third of the right arm a circumscribed mass of cystlike formation, measuring 14 cm. in the longitudinal and 8.5 cm. in the transverse diameter. The cortex was ill defined and showed a tendency to blend with the soft tissues. There were numerous striae, or trabecular

markings, giving the tumor a telangiectatic appearance. The reticulation had more of a lacelike effect. The shaft of the humerus in the region of the tumor was completely destroyed. No other bones were involved.

From September 9 to October 25 the patient was given high voltage roentgen therapy at 200. kilovolts and a target distance of 50 cm., with a filter of 1 mm. of aluminum and 0.5 mm. of copper and two ports of entry, 1,674 roentgens being used over each port. From Dec. 13, 1937, to Jan. 5, 1938, the Theraeus filter was substituted for the aluminum and copper filter, and 832 roentgens was used over the port; there were still two ports of entry, anterior and posterior, each being 10 cm. in diameter.

These high voltage roentgen treatments relieved the pain. After the last treatment the patient was advised to have the arm amputated and this was done by Dr. John Bacon at York Hospital January 17.

March 12 a film of the chest showed slight fibrosis but no evidence of metastasis. There was some cardiac enlargement associated with the hypertension from which the patient had been suffering for a number of years. On this date too an examination of the genito-urinary tract showed no evidence of a tumor in the region of either kidney.

After recovery from the operation the patient remained well and active, without indication of recurrent or metastatic neoplastic disease, until rather sudden death at home June 27, apparently from coronary occlusion. No autopsy was performed.

The Structure of the Lesion.—On dissection of the amputated arm, including longitudinal hemisection of the humerus, a fusiform swelling of the shaft of the humerus, 8 cm. in diameter, was found to extend downward 13 cm. from the surgical neck, replacing the shaft of the upper half of the bone. The interior was soft and friable, partly dark red, partly grayish red and partly pale grayish yellow. It included numerous small, smooth lined cysts, none over 1 cm. in diameter. Bloody fluid flowed from the mass on incision. The periphery, well demarcated, was composed of a shell of fibrous tissue in which ligamentous and muscular tissues were incorporated. Little of this periphery was ossified, and no calcified substance was found within the interior of the mass. The remainder of the medullary cavity of the humerus was filled with dark red marrow, which was not well demarcated from the substance of the tumor.

Microscopically, most of the substance of the tumor, including almost all its interior, was seen to be necrotic. Viable portions about the periphery consisted of ramifying columns of cells with bulky clear cytoplasm and rather pale vesicular nuclei, in most of which one or more prominent nucleoli were seen. These cells were moderately pleomorphic. Although in some places they appeared as solid cords, in general they surrounded lumens. Some lumens were narrow and empty, while others were filled with blood. Some of the blood-filled lumens were wider than the diameter of the low power microscopic field, with long narrow papillary projections of the bulky cells suspended in them. In addition, the tumor was traversed by numerous vascular channels of variable diameter, with a flattened endothelial lining, some of which were very wide and cavernous. There was but little supportive stroma; most of this was markedly hemorrhagic and edematous, giving the impression that these portions of the tumor were embedded in pools of blood. A thick fibrous capsule bordered the tumor but was poorly developed where the tumor met the marrow. Invasive capacity at the periphery nowhere was apparent. Vascular invasion was not observed.

COMMENT

Despite scattered case reports, the chief source of knowledge of angio-endothelioma of bone, of which we regard the foregoing case to be an example, is Ewing's¹ now classic book "Neoplastic Diseases." His description of the lesion as a solitary, bulky, cystic or telangiectatic tumor of the shafts or ends of long bones, occurring in adults, fits our case and undoubtedly is typical, but, as Crowell² has pointed out, the lesions are not all bulky and not all cystic. They expand and destroy the shaft and often penetrate the adjacent soft tissues.

2. Crowell, N. C.: Personal communication to the authors.

Fig. 2.—The gross specimen. A bulky fusiform swelling had replaced more than the upper half of the shaft of the humerus. Very little of the surface was osseous.

Fig. 3.—The bisected specimen after amputation, with the lacelike pattern accentuated. The fracture occurred at the time of amputation.

The absence of demonstrable pulmonary metastases in our case is in keeping also with Ewing's statement that these occur later than in osteosarcoma. In our case too the changes described by Ewing of the microscopic features of angio-endothelioma of bone in that the tumor presented solid columns, solid acinar groups and alveoli and channels composed of, or lined by, large cuboidal or cylindric cells with bulky clear cytoplasm, sharply defined cell walls and small nuclei.

Although it is true that such a structure is compatible with metastatic adenocarcinomas of the adrenal gland and of the kidney, there was no indication of a primary lesion of these structures in our case. Ewing¹⁰ stated that it has been a long time since he has seen such a typical example of angio-endothelioma of bone, that he feels it should be so classified, but that

Fig. 4.—Longitudinal bisection of the humerus, showing the partly solid and partly cystic interior of the tumor. The pale tissue composing the bulk of the tumor was in a state of coagulative necrosis, the probable effect of irradiation.

somehow he fears that a fat cell tumor could assume such a configuration. Since receiving his communication we have stained frozen sections of formaldehyde-fixed tissues with sudan III, and, although fat was demonstrated in areas of degeneration and necrosis, the viable and more mature neoplastic cells did not have the fat content characteristic of lipogenic neoplasms. Broders¹¹ agrees with the diagnosis of hemangio-endothelioma of bone, of the type which resembles adenocarcinoma of the kidney, or so-called hypernephroma, and regards this tumor as of grade 1 malignancy.

Three features of the structure may bear emphasis. There was destruction of bone without formation of bone. The expanded cortex had been replaced, except for a few fragmentary osseous remnants, by a stiff fibrous tissue shell. The fact that all the mass except the periphery was in a state of coagulative necrosis indi-

cated the radiosensitivity of the lesion, the failure of reduction in size after irradiation undoubtedly being due to the coagulated state of the interior and the lack of collapsibility of the stiff fibrous wall.

It may be well to add a paragraph distinguishing the lesion we have described from that designated as

Fig. 5.—Viable periphery of the tumor under low power. The cysts are seen to have a telangiectatic pathogenesis. The fundamental structure of the tumor is seen to be represented by acini of large clear cells, some having blood-filled lumens.

angioma of bone or as hemangioma of bone. The latter lesion is characterized—despite a roentgenologic soap bubble-like appearance—clinically by a benign course, anatomically by a subcortical location and histologically by the usual well differentiated structure of any pure angioma. Geschickter and Copeland¹² ably portrayed these features. Undoubtedly many angio-endotheliomas of bone have been classified as benign angiomas. Confusion too has existed between angio-

Fig. 6.—In higher magnification the cells of the neoplasm are seen to exhibit but little pleomorphism; the cytoplasm is bulky and relatively clear; the nuclei, although here appearing hyperchromatic, were vesicular, with macronucleoli.

endothelioma and endothelial myeloma, known as Ewing's sarcoma, since both were described by Ewing and since both are regarded as having an endothelial histogenesis.

SUMMARY

Angio-endothelioma of bone occurred in the shaft of the humerus of a woman aged 54. In one and one-half years it reached a size of 13 by 8 by 8 cm. It expanded and destroyed the shaft but was well demarcated from soft tissues. It was multilocularly cystic but chiefly solid, contained blood and roentgenologically was characterized by a soap bubble-like appearance. Blood-filled tubular columns of cells having bulky clear cytoplasm characterized it microscopically. After preoperative irradiation, only the periphery of the tumor was viable at the time of amputation. The patient died suddenly six months after amputation, apparently from coronary occlusion; no autopsy was performed. There had been no evidence of recurrence, of metastasis or of any tumor elsewhere in the body.

ABSTRACT OF DISCUSSION

DR. CHARLES F. GESCHICKTER, Baltimore: A few years ago it would have been embarrassing to open this discussion, because I was convinced there wasn't any such thing in bone as angio-endothelioma; but today we have to admit that all forms of pathologic involvement of the bone of a neoplastic character have not been described. The authors have recorded every case in the literature which I would include if I had to write on this subject. Their case looks as if it would be metastatic hypermyeloma of the kidney. The first experience with a case that helped me change my mind was in the rib and it looked like this tumor was vascular. The rib was resected and there never has been a recurrence of the primary tumor, and that was eight years ago. In my second case I diagnosed from the roentgenogram a primary benign giant cell tumor. It was explored, thought to be metastatic, and the patient died without a primary source demonstrable at autopsy. We know these tumors in the rib are related to the mesothelial of the pleura and, in the ends of bones near joints, to the synovial membrane. They might be called mesothelioma or synovioma of bone. The only objection to the term "endothelioma" is that it has been so widely misused. My conception is that these tumors arise from primitive mesoderm around joints and may occasionally be found in bone. The important point of view from the standpoint of radiology is that there are such tumors, usually in the ribs, occasionally in the ends of the bones or about the joints. They are not metastatic, they are moderately radio sensitive but not radio curable, and these patients should have the benefit of radical surgery. If in doubt, one is doing a better job if one treats it as primary rather than secondary growth.

DR. JOHN T. MURPHY, Toledo, Ohio: Bone tumors are rare. If you see one, try and follow it as carefully as you can, from a radiologic and clinical standpoint. The clinical course of the disease is the final test of the diagnosis. If you see a bone tumor and you make two standard views and it is an early case, you are not completely examining the patient. Plates should be made from many angles, so that the lesion can be examined all the way round. Stereoscopic films also should be made. If cases are examined this way the radiologic diagnosis of bone tumors can be improved.

DR. J. FLETCHER LUTZ, York, Pa.: From a radiologic standpoint little has been done on this particular tumor. I showed the roentgenograms of this tumor to numerous radiologists at the International Congress of Radiology at Chicago and it was not once intimated that the tumor might be an angio-endothelioma of bone. I showed it to Dr. Murphy and he said "I would like to see a biopsy." He would not commit himself. I would like also to quote the late Dr. Bloodgood, with whose views I know Dr. Geschickter is familiar. Dr. Bloodgood said that even the most eminent pathologists, when they have to depend on a slide alone, frequently make mistakes and that it was only a correlation of all the factors in the case that made a correct diagnosis possible.

GRANULOCYTOPENIA IN SULFAPYRIDINE THERAPY

VERA B. DOLGOPOL, M.D.

AND

HAROLD M. HOBART, M.D.

NEW YORK

The recent introduction of sulfapyridine as a chemotherapeutic agent offered the possibility of successful treatment of infections caused by the pneumococcus, irrespective of its type. This drug was also found to give encouraging results in the treatment of miscellaneous other infections (streptococcal, gonococcal and others) and is consequently being used quite extensively.

Whitby¹ and Wien,² in their animal experiments, found sulfapyridine to be less toxic than other sulfonamide preparations, and it was thought for some time that this drug would not cause any depression of the function of the bone marrow as had been observed in a number of cases of neoprontosil and sulfanilamide therapy.

Several series of observations on sulfapyridine therapy in large groups of patients failed to reveal any grave drop in the number of white blood cells (Evans and Gainsford³ 100 cases, Rosenthal⁴ 150 cases, Anderson and Dowdeswell⁵ 50 cases). The lowest figure obtained by the first two authors in one case was 4,200 white blood cells per cubic millimeter of blood.

Lloyd and Johnson,⁶ however, in a series of 250 patients treated with sulfapyridine noted that in a small number a slight but definite leukopenia occurred, with a decrease in the number of polymorphonuclears; the erythropoietic system was apparently not affected. No figures of actual blood counts were mentioned in the article. On the basis of their observations the authors warned about prolonged treatment with sulfapyridine without a close watch over the blood count.

In the same issue of the *Lancet*, Johnston⁷ reported a case of granulocytopenia following sulfapyridine therapy in puerperal sepsis. The lowest white blood cell count was 1,200 cells, with 8 per cent polymorphonuclears; the subsequent examinations of the blood showed slightly higher total figures for the white blood cells and from 0.5 to no polymorphonuclears. The patient died of septic endocarditis. The brief necropsy report makes no mention of the examination of the pharynx or of the bone marrow.

A few weeks later Coxon and Forbes⁸ reported a nonfatal agranulocytic angina in a patient with typhoid who was treated with sulfapyridine for thrombophlebitis. The total number of white blood cells fell to 1,000, with no polymorphonuclears. The authors pointed out that, although the action of the drug was definitely implicated in causing granulocytopenia, the natural leukopenia of the typhoid could be considered as a contributing factor in the development of the condition.

In a recent issue of THE JOURNAL two papers briefly mentioned cases of depression of the bone marrow.

Barnett and his associates,⁹ in the addendum to their paper, communicated that one of their patients developed granulocytopenia with tonsillitis (75 white blood cells per cubic millimeter of blood, with no granulocytes). Although the number of white blood cells rose subsequently to 22,500, the patient died of a complication of the agranulocytic angina (hemorrhage from the incised cervical lymph nodes and from the pharynx). In another case of their series a single count of 4,800 white blood cells was recorded.

Flippin and his co-workers¹⁰ have observed a leukopenia of 1,800 cells per cubic millimeter "with a normal

To this series of observations, showing the possibility of depression of the bone marrow by sulfapyridine, we add two cases of granulocytopenia and two cases of definite leukopenia. One case of granulocytopenia complicated by a mild aplastic anemia was fatal. These cases were observed at the Willard Parker Hospital in a series of thirty-five cases of pertussis and pneumonia treated with sulfapyridine.

REPORT OF CASES

CASE 1.—*Granulocytopenia.* A Negro girl aged 4 years, who had had pertussis since Jan. 1, 1939, was admitted to the Willard Parker Hospital January 25, when the cough had become more severe with emesis and bronchitis. The temperature was normal. There were no other complications.

TABLE 1.—Granulocytopenia in Case 1 After 49 Gm. of Sulfapyridine

Date	Blood											Therapy	Sulfa- pyridine in Blood	Plat- lets

differential.”¹¹ The authors also observed in several instances a marked reduction in the number of red blood cells and of the amount of hemoglobin.

Hodes and his associates¹² have seen five mild cases and one severe case of granulocytopenia in their series of seventy-one cases. In one case the white cell count was 4,200 per cubic millimeter with 8 per cent granulocytes.

Cases of significant granulocytopenia were seen also by Bullowa.¹³

February 5, twelve days after admission, the temperature was 104 F. and respirations were 50 per minute. Physical signs of pneumonia were present in the area of the right lower lobe and were confirmed by x-ray examination. Sputum (pharyngeal swab) revealed a type VI pneumococcus. There was no growth on blood culture.

Sulfapyridine therapy was started February 5. Two Gm. was given as the initial dose and 3 Gm. daily as the maintenance dose. The temperature returned to normal within forty-eight hours and the patient seemed improved. The blood concentration of sulfapyridine at this time was 10 mg. However, physical signs of pneumonia persisted and sulfapyridine administration was continued until February 13. Twenty-five Gm. was the total amount of the drug given until this time.

February 15, two days after the sulfapyridine was discontinued, the temperature rose to 103 and respirations to 40 per minute. The child became toxic and dyspneic. Physical signs of pneumonia persisted in the right side of the chest and x-ray examination revealed a consolidation of the right middle lobe. Examination of a pharyngeal swab showed a pneumococcus type VI once more, and the blood culture was sterile. Sulfa-

11. As the absolute number of polymorphonuclear leukocytes in the blood of a small child is usually above 2,500 and in an adult over 3,500, a total count 1,800 cells must be regarded as a significant neutropenia, irrespective of a normal differential count.

12. Hodes, H. L.; Stiffer, W. C., Jr.; Walker, Ethel; McCarty, Maclyn, and Shirley, R. G.: The Use of Sulfapyridine in Primary Pneumococcal Pneumonia, J. Pediat. 14: 417 (April) 1939.

13. Bullowa, J. G. M.: Personal communication to the authors.

pyridine was started again with the same dosage but with no apparent response.

The concentration February 17 was 9 mg. per hundred cubic centimeters of blood. Rales were also heard in the left lung at this time.

February 17, 80,000 units of type VI antipneumococcus rabbit serum was given intramuscularly. The temperature came down

Fig. 1.—Left tonsil: Erosion of the epithelium. N, necrotic areas; C, clusters of cocci. Hematoxylin-eosin; slightly reduced from a photomicrograph with a magnification of 135 diameters.

to 100 F. within forty-eight hours and the child seemed improved.

February 21 the patient appeared pale and sulfapyridine therapy was discontinued. A total of 49 Gm. of the drug had been given in fourteen days over a period of sixteen days. The temperature was 100 F. and respirations were 40 per minute.

TABLE 3.—Blood Counts in Case 3

Date	Erythrocytes	Hemoglobin	Leukocytes	Neutrophils	Lymphocytes	Monocytes	Eosinophils	Therapy	Sulfapyridine in Blood
1/18	7,000	39% = 2,730	56	4	..	Sulfap.

2/3	Trace
2/4	65	4,200	24% = 1,008	76	Discontinued	

The signs of consolidation persisted in the right side of the chest. On the same day a blood count revealed a granulocytopenia. Liver extract, pentnucleotide and blood transfusions were given with no response. Table 1 shows the blood picture, the therapy and the condition found in a smear from bone marrow.

The patient became progressively worse. February 24 the temperature was 104 F. and respirations 40 per minute. The liver and spleen became enlarged. Physical signs and x-ray examination showed the pneumonic process to be spreading. The blood culture taken February 17 had shown no growth.

February 28 the patient was seen in consultation by Dr. Nathan Rosenthal. In view of a low red blood cell count and a diminution of the number of platelets, his diagnosis was granulocytopenia and aplastic anemia.

February 28 a few small ulcerations appeared on the left tonsil.

March 1 the temperature was 106 F. and the respirations were 50 per minute. Swabs from the pharynx and larynx

showed a pneumococcus type I. The child died March 1 before further therapy could be administered. A blood culture taken on the day of death showed the presence of the type I pneumococcus.

NECROPSY ¹⁴

The necropsy was performed three and one-half hours after death by Dr. Raymond B. Miles, assistant medical examiner, and by Dr. Vera B. Dolgopol.

The body was well developed and well nourished. The abdomen was distended. The umbilical ring was open, but there was no herniation of the intestine. No evidence of obstruction was found.

TABLE 4.—Blood Counts in Case 4

Date	Erythrocytes	Hemoglobin	Leukocytes	Neutrophils	Lymphocytes	Monocytes	Therapy	Sulfapyridine in Blood
1/26	3,800,600	70	10,000	53% = 5,300	47	..	Sulfap.

The tonsils were rather large. Two minute reddish spots were present on the left tonsil, but, aside from this small lesion, the tonsillar, pharyngeal and lingual mucous membranes were pale and showed no necrosis.

Microscopically the right tonsil was slightly congested, but showed no other evidence of inflammation. The left tonsil showed erosion of the epithelium in two areas. In one of these areas, in a crypt, there was incipient necrosis of the substance

Fig. 2.—Lobar pneumonia: The exudate consists of erythrocytes, fibrin and a small number of mononuclear cells on the periphery of the alveoli. Hematoxylin-eosin; slightly reduced from a photomicrograph with a magnification of 135 diameters.

of the tonsil, with clusters of cocci and rare lymphocytes in the necrotic tissue. No polymorphonuclears were seen (fig. 1).

The larynx, trachea and bronchi presented a normal gross and microscopic appearance.

The upper lobe and a part of the middle lobe of the right lung were consolidated, purple and covered with a small amount

14. Dr. Miles gave us permission to report the pathologic examination in this case.

of fibrinous exudate. The cut surface was dull red but rather dry, with evidence of fibrin in the alveoli. The greater part of the left lower lobe was atelectatic. The rest of the tissue of both lungs was air holding.

Microscopic sections from the consolidated parts of the right lung presented a lobar consolidation of an unusual appearance. The central portions of the alveoli were filled with red blood cells and fibrin, while on the periphery, along the alveolar walls, a ring of mononuclear cells was present consisting of lymphocytes and cells of the alveolar lining (fig. 2). No polymorphonuclears were seen. Capsulated diplococci were present in the exudate of some alveoli.

The heart weighed 90 Gm. The right ventricle was distended but the myocardium was firm. The valves were intact.

Microscopic sections showed an early zenkerian degeneration. Small collections of fibroblasts, lymphocytes and plasma cells were present around small coronary branches.

The liver weighed 680 Gm. The parenchyma was quite firm; microscopically it showed albuminous degeneration.

The spleen weighed 95 Gm. and showed a marked congestion both grossly and microscopically.

The kidneys weighed 85 Gm. each. The cortex bulged slightly. Microscopically the tubular epithelium showed a moderately severe albuminous degeneration. Albuminous material was present in some Bowman's capsules. A slight infiltration with lymphocytes was present around several veins situated at the border of the cortex and medulla.

The small intestine, rectum and vagina were normal.

The bone marrow of the sternum and of a lumbar vertebra was red but could not be squeezed out for smears. The ribs contained only a minimal amount of marrow, so that the marrow spaces appeared to be empty.

Microscopic section from the bone marrow of several bones showed a slight decrease in the number of nucleated cellular elements in some areas but was not depleted as a whole (fig. 3). The cells were for the most part immature bone marrow cells, many of them with processes that held them to the stroma of the bone marrow. A small number of granular myelocytes and one or two polymorphonuclears were seen. The reticulum cells were prominent. Many normoblasts were scattered throughout the sections but they were not arranged in erythroblastic foci. The megakaryocytes were quite numerous. Many lymphocytes were present. The sinusoids were distended and contained many red blood cells and rare mononuclear cells.

Type I pneumococcus was cultured from both lungs and from the heart's blood.

CASE 2.—Granulocytopenia. A Negro girl aged 1 year was admitted to the Willard Parker Hospital Feb. 3, 1939, with a diagnosis of pertussis and bronchopneumonia. Breath sounds were diminished in both upper lobes of the lungs and many coarse rales were heard throughout the chest. The temperature was 103.6 F. and respirations were 60 per minute. X-ray examination revealed no consolidation at this time.

As the clinical picture was suggestive of pneumonia, sulfapyridine therapy was started February 3 with an initial dose of 2 Gm. and a maintenance dose of 2 Gm. daily. The temperature came down to 99 F. within twenty-four hours but it continued to range from 99 to 101 for the next ten days and the physical signs of pneumonia persisted until February 16. Sulfapyridine therapy was discontinued February 18, a total amount of 27 Gm. of the drug having been given during a period of fifteen days.

February 21 the patient seemed to be in good condition and convalescing satisfactorily. The chest was normal on physical examination. On the same day the blood count showed a suppression of leukocytes. Four days later there was a complete granulocytopenia. In the course of blood examinations it was found that the father and mother as well as the child had positive Wassermann reactions.

Blood transfusions, pentnucleotide and liver extract therapy was instituted February 25. Within two days the blood began to show a response. March 7 as indicated on table 2 the blood first showed a normal differential count.

During the time the infant had granulocytopenia, consolidation developed in the right upper lobe on February 24. The temperature was elevated to 102-103 F. for four days. The sputum did not reveal any pneumococcus and the blood culture was sterile. February 28 a small ulceration developed on the mucous membrane of the mouth and healed in six days. At the height of granulocytopenia the liver became enlarged and examination of the urine showed hyaline casts as well as granular casts and a few red blood cells. The urine cleared up after seven days.

X-ray examination of the bones March 13 revealed no evidence of syphilitic changes.

The patient was discharged March 17 in good condition.

CASE 3.—Leukopenia. A white infant girl aged 18 months was admitted to Willard Parker Hospital Jan. 18, 1939, on the fifty-first day of pertussis. On January 28 she developed

Fig. 3.—Bone marrow: Polymorphonuclears are absent. R, reticulum cells; M, megakaryocytes. Hematoxylin-eosin; slightly reduced from a photomicrograph with a magnification of 680 diameters.

a bronchopneumonia, with no pneumococcus in the sputum. Sulfapyridine therapy was started January 29 with 2 Gm. as the initial dose and 2.5 Gm. daily as a maintenance dose. January 30 the concentration of sulfapyridine in the blood was 7.7 mg. per hundred cubic centimeters. The administration of sulfapyridine was discontinued after six days because of a low white blood cell count. The total intake of sulfapyridine was 13 Gm.

The child made an uneventful recovery and was discharged February 16.

CASE 4.—A white infant girl aged 10 months was admitted to Willard Parker Hospital Jan. 25, 1939, with the diagnosis of pertussis and pneumonia. The temperature was 102 F. The physical examination revealed consolidation of the left lower lobe; these observations were confirmed roentgenologically. The sputum showed no pneumococcus.

Sulfapyridine therapy was started January 25. The initial dose was 0.5 Gm. and the maintenance dose 1.5 Gm. daily. On the fourth day of treatment, after an intake of 3 Gm., the white blood cell count showed 4,300 cells, with 14 per cent neutrophils. As the concentration of sulfapyridine in the blood was minimal, the drug was not discontinued.

Eight days later the blood picture showed an increase in the total number of white blood cells and a higher percentage of neutrophils. On the same day the temperature became normal and sulfapyridine was discontinued. The total intake of sulfapyridine was 13 Gm. in eleven days. The patient was discharged in good condition February 25.

COMMENT

It is evident from the review of the literature and from the cases presented that sulfapyridine may occasionally depress the function of the bone marrow. This effect of the drug on the bone marrow is not surprising, as sulfapyridine, or 2(para-aminobenzene sulfonamide) pyridine contains the benzamine group, which, according to Kracke and Parker,¹⁵ is responsible for the injurious action of a number of drugs on the myelogenous tissue.

Of the five cases of granulocytopenia, three were fatal.

The action of the drug on the bone marrow apparently consists mainly in the arrest of maturation of the leukopoietic elements. The bone marrow in our case 1, while not aplastic, showed a virtual absence of polymorphonuclears, a small number of myelocytes and numerous immature cells. After patient 2 began to respond to the treatment, immature myelogenous cells appeared in the circulating blood. The erythropoietic elements, however, may also be affected, as seen in case 1, in which the number of the nucleated red blood cells in smears from the bone marrow was greatly reduced, and no erythropoietic foci were found in the sections from the bone marrow.

Several cases of a transient but definite leukopenia were mentioned by different authors, and two are presented in this report. The transient leukopenia, while not dangerous in itself, is significant, as it indicates the tendency of sulfapyridine to depress the myelogenesis in some individuals.

It is worthy of attention that the damage to the bone marrow may become manifest only after the discontinuance of the sulfapyridine therapy, as in the cases of Barnett and his associates, of Hodes and his associates (case E. J., table 1) and in our case 2. It is therefore suggested that the hematologic observations be continued for two weeks after the cessation of a prolonged sulfapyridine treatment.

It would be of practical importance to establish (1) whether the sulfapyridine is deleterious to the bone marrow when a large total amount of the drug is administered during a long course of treatment, (2) whether a high concentration of sulfapyridine in the blood plays an important role, (3) whether the drug is toxic in ordinary doses for certain sensitive individuals, (4) whether a course of sulfapyridine therapy sensitizes the patient to the drug so that it becomes injurious to the bone marrow on resumption of the therapy after an intermission, or (5) whether it is injurious only to the bone marrow already damaged by the original disease for which the treatment is given.

1. All five patients with granulocytopenia had taken large total amounts of sulfapyridine before the bone marrow was affected. Johnston's patient, an adult, had had 54 Gm. of the drug in thirteen days before the bone marrow was affected. The patient of Coxon and Forbes, also an adult, had had 54 Gm. of sulfapyridine in seventeen days before granulocytopenia was noticed. The patient of Barnett and his co-workers, a 10 year old girl, had taken 80.9 Gm. in seventeen days over a twenty-six day period. Our patients, 4 years and 1 year old, had received 49 Gm. and 27 Gm. respectively in two weeks—excessively large amounts for the size of the patients. The highest total dosage of sulfapyridine on record, administered to adults without any damage to the bone marrow, is 49.5 Gm. and 51 Gm. (Evans and Gainsford).

2. The highest concentration of sulfapyridine in the blood in our fatal case of granulocytopenia was 10 mg. per hundred cubic centimeters. Other workers, however, have observed concentrations up to 18 mg. of free sulfapyridine without deleterious results, so that a high concentration of free sulfapyridine in the blood *per se* is probably of less importance than a high total intake of the drug during the course of treatment.

3. An individual sensitivity to sulfapyridine probably plays a role in the development of neutropenia in some cases. Patient 4, with a leukopenia of 4,300 cells and 14 per cent neutrophils (602 neutrophils per cubic millimeter) showed this drop in the number of white cells after the intake of 3 Gm. of sulfapyridine, with only a trace of the drug in the blood at any time during the treatment. Despite the continuation of the administration of sulfapyridine, the number of white cells increased to 8,250, with 36 per cent neutrophils. In this case the absence of a severe damage to the bone marrow in a sensitive individual despite the continuation of sulfapyridine therapy could probably be explained by a rapid elimination of the drug by the kidneys. In a case of Hodes and his associates (C. K., table 2) a moderate granulocytopenia developed after only two days of treatment with 5.7 mg. of sulfapyridine per hundred cubic centimeters of blood.

4. In connection with various toxic manifestations during sulfapyridine therapy the question arose in the minds of a number of clinicians whether a course of sulfapyridine treatment might sensitize the patient, predisposing him to toxic reactions on resumption of the administration of the drug. This possibility has to be considered also in analyzing the causes of granulocytopenia in sulfapyridine therapy. Three patients with granulocytopenia had an interval of from two to three days between the two courses of sulfapyridine (patients of Johnston, Barnett and his associates and our patient 1). These cases could be considered as possible instances of toxic reactions due to sensitization to the drug. Two other patients, however (Coxon and Forbes, and our patient 2) had had a single course of treatment which presented no possibility of sensitization. The total intake of sulfapyridine in all five cases of granulocytopenia was so great that we are inclined to regard this factual evidence as a more likely cause of the damage to the bone marrow than the theoretical consideration of sensitization. The irrelevance of the second course of sulfapyridine therapy *per se* to the depression of the bone marrow is supported also by two observations of Hodes and his associates on patients who had had granulocytopenia during the first course of the therapy but showed no recurrence of that manifestation during the second course.

5. Johnston in his case could not exclude the possible damage to the bone marrow by the overwhelmingly active streptococcal infection, in addition to the large amount of sulfapyridine administered. Coxon and Forbes, while realizing that the drug was probably responsible for granulocytopenia, considered that the original disease, typhoid, might have made the bone marrow more susceptible to sulfapyridine. The patient of Barnett and his associates was apparently over her original infection at the time granulocytopenia developed. In our cases it is unlikely that pertussis had any influence on the depression of the function of the bone marrow. While it is true that in pertussis the percentage of neutrophils is often markedly reduced, there is usually no actual neutropenia, as the total number of white blood cells is high. The absolute number of

15. Kracke, R. R., and Parker, F. P.: Etiology of Granulopenia (Agranulocytosis), *J. Lab. & Clin. Med.* 19:799, 1934.

neutrophils in pertussis, despite the low percentage, may even rise above the normal figures.¹⁶ In our case 2 the roentgenologic study failed to show any involvement of the bones. The rapid response to the therapy indicates that the bone marrow in all probability was essentially normal. However, the possibility that her bone marrow was to some extent damaged by the congenital syphilis cannot be denied. It would seem that in at least two cases of granulocytopenia (Barnett and his associates and our case 1) the excessively large total intake of sulfapyridine alone was responsible for the condition. In two cases there was possibly a joint damaging action on the bone marrow by the drug and by the original infection, and in one case congenital syphilis could have been a predisposing factor. Pertussis can probably be excluded from contributing to the depression of the myelogenous elements.

It is apparent from perusing the literature on sulfapyridine therapy, and particularly in reference to the high dosage of the drug administered in the cases of granulocytopenia, that there is a tendency to use excessively large amounts of sulfapyridine. While trying to accomplish a high initial concentration level of sulfapyridine in the blood, as recommended by Whitby, his further suggestion to keep the blood level at 8 mg. per hundred cubic centimeters and to use 23 Gm. of the drug per week for an adult is sometimes overlooked.

SUMMARY

A review of the recent literature shows that three cases of granulocytopenia and a number of cases of leukopenia were observed in the course of sulfapyridine therapy.

Two new cases of granulocytopenia and two cases of leukopenia are reported in children with pertussis and pneumonia treated with sulfapyridine.

In the fatal case of granulocytopenia reported here, the patient lived nine days following a complete disappearance of polymorphonuclears. Minimal tonsillar lesions appeared two days before the patient died of lobar pneumonia. The pneumonic exudate was free of polymorphonuclear cells. The bone marrow was immature. Aplastic anemia developed in the course of granulocytopenia but the megakaryocytes remained intact.

In the second case of granulocytopenia immature cells of the myeloid group appeared in the circulating blood with the beginning of recovery and were gradually replaced by more mature forms.

All five patients with granulocytopenia received large total amounts of sulfapyridine during the course of treatment.

In at least two cases of granulocytopenia sulfapyridine was apparently the only cause of the condition. In the other three cases a coincident damage to the bone marrow by the original infection or by a previous infection may be considered to be a contributory factor in the development of granulocytopenia.

In two cases granulocytopenia developed after the discontinuance of the sulfapyridine therapy.

CONCLUSIONS

A high total intake of sulfapyridine may cause granulocytopenia.

The damage to the bone marrow consists in depression of maturation of myeloid cells. The erythropoiesis may also be occasionally disturbed.

Blood counts should be made twice a week during sulfapyridine therapy and continued for two weeks after the withdrawal of the drug.

ADDENDUM.—Since the paper was submitted for publication, another case of leukopenia during sulfapyridine therapy was observed at this hospital, in a 16 month old male infant suffering from pneumococcal pneumonia type XIV. On admission the blood count showed 10,000 white cells per cubic millimeter of blood, with 76 per cent, or 7,600, neutrophils. The child received 7 Gm. of sulfapyridine in four days; the drug was discontinued because of leukopenia (4,200 white blood cells per cubic millimeter, with 25 per cent, or 1,050, neutrophils). Eight days later the white cell count rose to 21,700 per cubic millimeter of blood, with 71 per cent, or 15,107, neutrophils. The administration of the drug was resumed, and the child received another 7 Gm. in three days. The white cell count went down to 8,500 per cubic millimeter of blood, with 42 per cent, or 3,500, neutrophils, and the drug was withdrawn. The patient made an uneventful recovery.

THE TREATMENT OF AURICULAR FIBRILLATION WITH QUINIDINE AND STRYCHNINE

REPORT OF FORTY-ONE CASES

HARRY L. SMITH, M.D.

ROCHESTER, MINN.

AND

EDWARD W. BOLAND, M.D.

Fellow in Medicine, the Mayo Foundation

LOS ANGELES

There continues to be considerable variance of opinion regarding the advisability of attempting to restore normal cardiac rhythm by the administration of quinidine in cases of auricular fibrillation. The greatest variance of opinion concerns the type of case in which this should be attempted, the amount of permanent benefit, the size of the dose and the method of administration.

PHYSIOLOGIC ACTION OF QUINIDINE

Quinidine is an alkaloid of cinchona and is isomeric with quinine.¹ It is soluble in ninety parts of water and in ten parts of alcohol. It is readily absorbed from the upper portion of the intestinal tract. When given intravenously to animals, it disappears from the blood stream in about five minutes. It is eliminated chiefly by the kidneys.

Weiss and Hatcher² found that when quinidine is administered to cats it is almost entirely eliminated in from three to four hours. We found a small trace of the drug in the urine of human beings one hour after the oral administration of 5 grains (0.3 Gm.); the maximal amount was found from two to three hours after administration and only a trace was found at the end of four hours. The drug is supposed to be partially destroyed by the liver.

Most of the investigators who studied the action of the drug on animals and anesthetized the animals found that the sinus rate was slowed, the PR interval was prolonged and the intraventricular conduction was delayed. Some of these investigators found that the refractory

period was lengthened. The investigators³ who did not anesthetize the animals did not obtain these results. They found that the sinus rate was accelerated and that there was no prolongation of the PR interval. They did find, however, that the intraventricular conduction was delayed. We do not know a good explanation for the difference in the results obtained by these two groups of investigators unless the absence of anesthesia and the production of pain played an important role.

SYNERGY OF QUINIDINE AND STRYCHNINE SULFATE

It is our impression that quinidine and strychnine sulfate are synergists. We believe that quinidine is more efficacious if supplemented with strychnine sulfate than it is when administered alone and that smaller doses of quinidine are required if strychnine sulfate is also administered. We obtained this impression a few years ago while we were treating several patients who had auricular flutter. In three cases in which administration of quinidine for from ten to fourteen days did not have any appreciable effect on the auricular flutter, normal cardiac rhythm was reestablished by the administration of strychnine sulfate in addition to the quinidine. Two doses of strychnine sulfate were administered in one of the cases and three doses were administered in two of the cases. We do not have any other pharmacologic proof of this synergy.

MATERIAL

This paper is based on the results obtained in forty-one cases of auricular fibrillation. With one or two exceptions, these were consecutive cases of auricular fibrillation that were observed at the Mayo Clinic. The age of the patients varied from 20 to 76 years. Of the forty-one patients, one was in the third, five were in the fourth, nine were in the fifth, sixteen were in the sixth, nine were in the seventh and one was in the eighth decade of life. Thirty of the patients were men and eleven were women.

ETIOLOGY

The auricular fibrillation was classified as idiopathic in four cases; that is, it was the only evidence of organic heart disease. In five cases the fibrillation was the

result of hyperthyroidism; two of the patients also had hypertension and coronary sclerosis. There were six cases in which the auricular fibrillation was associated with hypertension and coronary sclerosis. In twelve cases it was due to rheumatic heart disease and in fourteen cases it was the result of coronary sclerosis.

STATE OF COMPENSATION

The compensation was good in twenty-five cases but a varying degree of congestive heart failure was present in sixteen cases. In twelve of the sixteen cases the heart failure was mild and in four cases it was severe.

DURATION OF AURICULAR FIBRILLATION

In most cases it is difficult to determine the time of onset of the auricular fibrillation. As far as could be determined, the time that had elapsed between the onset of the auricular fibrillation and the institution of treatment was one week in two cases, six weeks in four cases, from two to three months in seven cases, four months in four cases, six months in two cases, seven months in one case, ten months in one case, one year in seven cases, two years in five cases, three years in three cases, five years in two cases, seven years in one case, eight years in one case and ten years in one case. While these figures are not strictly accurate, we are reasonably certain that the auricular fibrillation had at least been present for the indicated time. It is rather interesting to note that the patient who had had auricular fibrillation for ten years had consulted the late Dr. Joe Miller at the time of the apparent onset of the fibrillation. At that time quinidine had been prescribed in small doses but normal cardiac rhythm had not been established.

AMOUNT OF QUINIDINE ADMINISTRATION

In most cases 5 grains (0.3 Gm.) of quinidine was administered every three hours and $\frac{1}{40}$ or $\frac{1}{30}$ grain (0.0016 or 0.0022 Gm.) of strychnine sulfate was administered three times a day, depending on the weight of the patient. The total amount of quinidine that was administered before normal cardiac rhythm was established was 10 grains (0.65 Gm.) in one case, 15 grains (1 Gm.) in three cases, 20 grains (1.3 Gm.) in six cases, 30 grains (2 Gm.) in eight cases, 40 grains (2.6 Gm.) in seven cases, 50 grains (3.3 Gm.) in three cases, 60 grains (4 Gm.) in four cases, 90 grains (6 Gm.) in one case, 100 grains (6.6 Gm.) in two cases, 120 grains (8 Gm.) in one case, 130 grains (8.65 Gm.) in one case, 165 grains (11 Gm.) in one case, 190 grains (12.6 Gm.) in one case, 200 grains (13.2 Gm.) in one case and 2,620 grains (175 Gm.) in one case.

In thirty-one, or 75.6 per cent, of the cases the amount of quinidine required to restore normal cardiac rhythm was 60 grains (4 Gm.) or less. In eight cases from 90 to 200 grains (6 to 13.2 Gm.), or an average of 124 grains (8.24 Gm.), was required. As previously stated, 2,620 grains (175 Gm.) was required in one case. This patient was a man who had rheumatic endocarditis and mitral stenosis. His left leg had been amputated because of acute occlusion of the femoral artery. Auricular fibrillation had been present continuously for seven years before the patient came to the clinic. A total of 135 grains (9 Gm.) of quinidine was administered in five days. During this period $\frac{1}{40}$ grain (0.0016 Gm.) of strychnine sulfate was administered three times a day. Auricular flutter developed on the fifth day and persisted for sixty-six days. The patient took a total of 2,620 grains (175 Gm.) of quinidine, or an average of about 40 grains (2.6 Gm.) a day; before normal

cardiac rhythm was established. The dose of quinidine was then reduced to 5 grains (0.3 Gm.), which was administered four times a day for a few days and then was administered three times a day. When the patient was examined one year after his dismissal it was found that the cardiac rhythm was still normal.

ONSET OF AURICULAR FLUTTER

In cases of auricular fibrillation it is relatively common for auricular flutter to develop while quinidine is being administered. In a review of the literature Warren⁴ found that auricular flutter developed in thirty-nine, or 14.8 per cent, of 263 cases of auricular fibrillation in which quinidine was administered.⁵ Once auricular flutter develops, it may continue permanently, it may revert to auricular fibrillation, or normal cardiac rhythm may return.

Auricular flutter developed in four, or 9.7 per cent, of the cases in this series. In one case it developed after the administration of 20 grains (1.3 Gm.) of quinidine, in two cases it developed after the administration of 65 grains (4.3 Gm.) and in one case it developed after the administration of 135 grains (9 Gm.). In one case the flutter lasted for sixty-six days before normal cardiac rhythm returned, in one case the flutter persisted permanently and in two cases it reverted to auricular fibrillation.

ILL EFFECTS OF QUINIDINE

Toxic Effects.—Nausea, vomiting, diarrhea, weakness and palpitation developed in four, or 9.7 per cent, of the cases in this series. In two of these cases the symptoms were mild but in two cases they were fairly severe. In the four cases the symptoms of toxemia developed after the administration of 40 grains (2.6 Gm.), 45 grains (3 Gm.), 65 grains (4.3 Gm.) and 210 grains (14 Gm.) respectively. In all these cases the administration of quinidine was discontinued at the onset of symptoms of toxemia.

Embolism.—Cerebral embolism did not occur while the patients were being treated or while they were under observation at the clinic. In three cases there was a history of cerebral embolism and hemiplegia. One of these patients had had a stroke two years before treatment was instituted and rather complete hemiplegia was still present when she came to the clinic. Another patient had had a stroke three months prior to the beginning of treatment. In the third case the treatment was started immediately after the development of hemiplegia; in this case normal cardiac rhythm was established and maintained by administration of a minimal amount of quinidine.

Peripheral Arterial Occlusion.—In no case did arterial occlusion occur while the patient was being treated. In three cases arterial occlusion had occurred before the treatment was begun. In one of these cases occlusion

of the femoral artery had necessitated amputation of the right leg three years before the patient came to the clinic. Another patient had had acute occlusion of the femoral artery which had necessitated amputation of the left leg below the knee. In the third case, in which the auricular fibrillation was associated with mitral stenosis, the treatment was started immediately after the occurrence of acute occlusion of both popliteal arteries; in this case, normal cardiac rhythm was established and maintained.

Sudden Death.—Sudden death occurred in three cases. One of these patients was a woman aged 45 who had chronic rheumatic endocarditis; myocardial insufficiency and a considerable degree of cardiac enlargement. Auricular fibrillation had been present for about six weeks. In addition, the patient had a huge hypernephroma on the left side. We were asked to see her and to evaluate the surgical risk involved. It was thought advisable to attempt to establish normal cardiac rhythm. Five grains (0.3 Gm.) of quinidine was administered every hour until three doses had been given. On the following morning, that is, on the second day of treatment, the cardiac rhythm was normal. On this day, four doses of 5 grains (0.3 Gm.) each of quinidine were administered. On the morning of the third day the patient felt very well when she awoke. About 10 a. m., after she had eaten breakfast and while she was sitting and talking to members of her family, she ceased talking and died very suddenly; that is, within a minute or two. A necropsy was not performed in this case.

The second patient who died suddenly was a man aged 57 who had an adenomatous goiter, hyperthyroidism and auricular fibrillation. He probably had had a previous hypertension. The auricular fibrillation had been present continuously for six months before he came to the clinic. Examination disclosed cardiac enlargement, grade 3. The auricular fibrillation continued after a thyroidectomy was performed. On the seventh day after operation a total of 15 grains (1 Gm.) of quinidine was administered. This was administered in doses of 5 grains (0.3 Gm.) and at intervals of three hours. On the morning of the eighth day after operation his cardiac rhythm was regular. On this day 5 grains (0.3 Gm.) of quinidine was administered every four hours until four doses had been given, and one dose of $\frac{1}{50}$ grain (0.0022 Gm.) of strychnine sulfate was administered. Auricular fibrillation was present on the following morning; that is, on the morning of the ninth day after the operation. On this day a total of 20 grains (1.3 Gm.) of quinidine was administered in doses of 5 grains (0.3 Gm.) and at intervals of three hours, and three doses of $\frac{1}{30}$ grain each (0.0022 Gm.) of strychnine sulfate were administered. The cardiac rhythm was regular on the morning of the tenth day after operation. That night the patient seemed to be somewhat restless. He went to the bathroom several times and during most of the night he slept in a chair. When his wife arose and shook him to awaken him because he was snoring loudly he died suddenly. He just slumped down in the chair and was dead. Necropsy disclosed that his heart was enlarged and dilated. The heart weighed 650 Gm. The coronary arteries were moderately sclerosed. No clots were found in the auricles or ventricles.

The third patient who died suddenly was a man aged 53 who had hypertension, coronary sclerosis, auricular fibrillation and cardiac hypertrophy. Auricular fibrillation probably had been present for several weeks before the patient came to the clinic. He had a moderate degree of congestive heart failure and was admitted to

the hospital. During the first five days that the patient was in the hospital he received $1\frac{1}{2}$ grains (0.1 Gm.) of digitalis three times a day. The administration of quinidine was started on the sixth day. On this day he received five doses of 5 grains (0.3 Gm.) each at intervals of three hours. Another dose of 5 grains (0.3 Gm.) of quinidine was administered on the morning of the seventh day. At about 8 a. m. his cardiac rhythm was normal. We saw the patient while we were making ward rounds with several physicians. He said that he felt unusually well. He was not dyspneic and he appeared perfectly comfortable. A few minutes later, while his wife and son were talking with him as he sat in bed leaning against a back rest, he ceased talking, slumped down in bed and died without any struggle. The postmortem appearances were similar to those in the previous case. The heart was greatly enlarged and dilated. Necropsy disclosed coronary sclerosis, grade 2, but there was no evidence of acute coronary occlusion. No clots were found in any of the chambers of the heart.

ANALYSIS OF RESULTS

In the past it has been believed that the production of embolism by the detachment of a clot was the real danger and the cause of death in cases in which quinidine was administered. In this series of forty-one cases, embolism did not occur while the patients were being treated or while they were under observation at the clinic. In the past the possibility of embolism has been the chief objection to the administration of quinidine. Some investigators⁶ have observed that the occurrence of embolism is not any more common in cases of heart disease in which quinidine is administered than it is in cases in which quinidine is not administered. We feel certain that this objection has been greatly overemphasized.

There were three sudden deaths in this series of cases. This is not a particularly high mortality rate in forty-one cases of rather severe heart disease. The mortality will vary greatly in different series of cases, as it depends on the severity of the heart disease present. It is a very high rate for this particular type of death. Very sudden death is a rare occurrence in any group of cases. By sudden death we mean death that occurs within a few seconds to one or two minutes. A certain percentage of patients who have pulmonary embolism will die suddenly. Patients with acute coronary occlusion as a rule do not die so quickly; they live, as a rule, several minutes—from ten to twenty minutes or an hour or longer.

Patients with cerebral vascular accidents usually live a few hours or longer. It is rather interesting to speculate on the mechanism of death in the cases in which the patients died very suddenly. We believe that it is probable that both the sino-auricular node and the auriculoventricular node became depressed for a sufficient period of time to produce death. In other words, we believe that the patients actually died of cardiac standstill. In each instance in which sudden death occurred, normal rhythm was restored before death occurred. In the three cases the hearts were rather markedly enlarged. In one case auricular fibrillation had been present for six weeks, in one case it had been present for six months and in the third case it had been present for one year. The amount of quinidine did not appear to be an important factor, as one patient received a total of 35 grains (2.3 Gm.) in two days, one a total

of 55 grains (3.6 Gm.) over a period of three days and one a total of 30 grains (2 Gm.) over a period of twenty-four hours.

Normal cardiac rhythm was reestablished or restored in thirty-three, or 80.4 per cent, of the forty-one cases. There were eight cases in which normal rhythm could not be reestablished or restored. Five of these eight patients had rheumatic heart disease. Three of the eight patients had hypertensive and arteriosclerotic heart disease. The percentage of cases in which different investigators have been able to establish normal cardiac rhythm has varied considerably. We think this depends largely on the type of patients that are selected for treatment. We are reasonably certain that if one could select his patients with sufficient care normal cardiac rhythm could be restored in almost 100 per cent of cases. Normal rhythm has persisted in this group of cases for varying lengths of time. In some cases it has persisted for two years and in a few cases it has persisted for four months. The average length of time has been approximately six months. Sufficient time has not elapsed since this study has been completed to warrant definite conclusions with regard to the permanence of the reestablished normal rhythm. However, there have been several authors who have observed their patients for a considerable number of years. Campbell and Gordon⁷ were able to establish normal cardiac rhythm in 64 per cent of 135 cases. In 34 per cent of these cases normal rhythm had been maintained for an average period of nearly four years and in 25 per cent of the cases it has been maintained for nine years. For a few days after normal rhythm was established, the patients usually received the same dose of quinidine that was administered previously. A few of the patients had short temporary relapses, but normal rhythm was readily restored by administration of the same doses of quinidine that had been given previously.

TYPE OF PATIENT WHO SHOULD RECEIVE QUINIDINE

It is, we believe, well established that hearts in which there is normal rhythm are more efficient than those in which there is auricular fibrillation, provided other factors are equal.⁸ The prognosis of auricular fibrillation depends solely on the severity of the associated cardiac damage. It is a well known fact that patients who have mild cardiac disease and permanent auricular fibrillation may live for years and follow a rather active normal life. This fact should be borne in mind when selecting patients who should be treated.

It seems to us that quinidine is especially indicated when the patients are young persons who have idiopathic auricular fibrillation but who do not have any other evidence of heart disease. The next group of patients who should receive quinidine are those who have a minimal amount of heart disease and who have had auricular fibrillation only a short time. Quinidine should be administered in cases in which auricular fibrillation is due to hyperthyroidism, is not associated with any significant evidence of organic heart disease and continues several weeks after thyroidectomy has been performed. Patients for whom the least amount of the

drug is required to establish normal cardiac rhythm are those who are about 55 or 60 years of age, have a moderate degree of coronary sclerosis, have a good degree of cardiac compensation and have had auricular fibrillation for a relatively short time. In most instances of this type, only a few doses of quinidine are required to restore normal rhythm and in a large percentage of cases normal rhythm can be maintained for many years. We believe that patients for whom it is most dangerous to administer quinidine are those who are elderly, who have rather serious hypertension and coronary sclerosis, with rather marked cardiac enlargement, and who have had auricular fibrillation for a long time. It probably is not advisable to attempt to establish normal rhythm with quinidine in any case of severe congestive heart failure. There is a group, however, which we believe is an exception to this statement. In this group the patients have considerable heart disease with varying amounts of heart failure and emboli continue to form. These emboli may be cerebral, pulmonary or may occur in the peripheral vessels. In this group of cases we believe that one is justified in taking a greater risk to establish normal rhythm. The patients are less likely to have emboli if normal rhythm can be restored. We believe that the possibility of clots being detached as emboli when the auricles resume their normal rhythm has been greatly overemphasized. We believe that the greatest danger in giving quinidine is the possible occurrence of sudden death. This danger has to be seriously considered and weighed against the benefit that the patient receives when normal cardiac rhythm is reestablished. In well selected cases, we believe that there is ample proof that this danger is slight. Patients whose normal rhythm is restored and maintained undoubtedly are greatly benefited.

ABSTRACT OF DISCUSSION

Dr. ROY W. SCOTT, Cleveland: The authors' observations on the effect of quinidine in restoring a sinus rhythm in cases of auricular fibrillation agree in general with those previously recorded. The early enthusiasm accorded quinidine has been tempered by the fact that the drug is not devoid of danger and, as the authors observed in their fatal cases, death often occurs suddenly of patients who exhibit no evidence of congestive failure. To avoid such accidents, care should be exercised in the selection of patients to receive quinidine and, before giving the drug to the patient with auricular fibrillation, it should be remembered that many patients do very well and survive for many years on a maintenance dose of digitalis. It seems fair to say that, the more damaged the heart, the more unsatisfactory are the results obtained with quinidine. Death may occur suddenly; the patient may fail to respond, or the restored sinus rhythm may persist for only a short time. I have found, as the authors have indicated, that the best results are seen in those cases in which fibrillation is not associated with any demonstrable evidence of organic heart disease. Good results are also seen in patients with hyperthyroidism who continue to fibrillate after thyroidectomy; if such patients are cured by operation, a sinus rhythm usually persists. Patients with rheumatic heart disease and mitral stenosis who are known to have had fibrillation only a short time and who have not had an attack of congestive failure usually respond satisfactorily to quinidine. Sooner or later, however, fibrillation reappears and it becomes increasingly difficult to establish a sinus rhythm which persists for any length of time. That quinidine is a valuable drug in the management of carefully selected cases of auricular fibrillation is well established but, as McKenzie predicted many years ago, digitalis remains the most reliable drug in the majority of cases of fibrillation associated with seriously damaged hearts.

Dr. F. J. HIRSCHBOECK, Duluth, Minn.: One of the important points the authors raised relative to the treatment of fibrillation was the question of the incidence of embolic deaths. No one probably has had a very great experience in sudden

death with the use of quinidine, because, if he had, he probably would discontinue its use. Obviously, much of what we have in the form of data devolves on records in the literature. I do not believe that pulmonary emboli are likely to be the cause of sudden death, because usually emboli that emanate from the heart are not of the large type that tend to cause rapid dissolution. Peripheral emboli, likewise, rarely cause sudden death. The only possibility to consider in an embolic death would be that of cerebral origin. If that were a common cause, our post-mortem statistics should show it definitely. If deaths in these cases are not of embolic origin (and I do not believe all of them, or possibly even the great majority of them are), they probably occur from some physiologic disturbance in the conduction mechanism in the heart, as has been indicated by the authors in their discussion of animal experimentation. Deaths occur particularly in cases of severe heart disease with chronic fibrillation. It is in this type of heart that quinidine is likely to be used for a long time and in rather large doses. So one tends to foster and favor the possibility of a sudden physiologic disturbance. The use of strychnine as a synergist with quinidine brings up two questions. If embolic deaths are common, and if they are the usual source of death, we must be careful in using a synergist like strychnine, because it may give us a false sense of security in that we may be able to use smaller doses of quinidine, bring about a normal rhythm in cases of more serious fibrillation and tend to favor more embolic deaths rather than less. If strychnine acts as a synergist on a pharmacologic basis with quinidine, we must find out by further use whether it is a physiologic synergist or an antagonist. One must think of that when one realizes that the authors reported three fatalities in forty-five cases.

Dr. MORRIS MARGOLIN, Omaha: What is the status of digitalis in the treatment of auricular fibrillation? What do you think of slowing the heart rate first with digitalis and then giving quinidine? Would you use quinidine and digitalis simultaneously?

Dr. S. A. WEISMAN, Minneapolis: We have been interested in quinidine in the treatment of auricular fibrillation at the University of Minnesota for nine years and our results have been quite satisfactory. The question of the dangers of quinidine causing emboli and sudden deaths is being constantly brought up. In 1923 Viko, Marvin and White reported 484 cases of auricular fibrillation treated with quinidine that they had collected from the literature and compared that group with 200 cases not treated with quinidine that they had collected from the records of the Massachusetts General Hospital. They found that there was little difference in the number of accidents in the two groups. In 1922 Robert Levy reported fifty cases of auricular fibrillation, twenty-five treated with quinidine and twenty-five treated in the usual manner. He had five accidents in the group not treated with quinidine and one possible embolus in the quinidine-treated group. Many deaths attributed to quinidine are not due to quinidine at all. A woman aged 26, who had a mitral stenosis and auricular fibrillation and who was decompensated, was given digitalis and later quinidine. While on this treatment she died suddenly. Shortly before her death her heart was fibrillating. The postmortem disclosed a large vegetation on the aortic valve and subacute bacterial endocarditis. The patient, however, had had no abnormal elevation of temperature or other definite signs that would lead one to suspect this diagnosis. A portion of the vegetation on the valve had broken off into the circulation and caused cerebral embolism and sudden death. Should a patient die while being treated with quinidine, the death is usually attributed to the use of this drug. But in many cases no emboli or thrombi are found. The cause of death is often undetermined. Mackenzie, Orr and White reported similar cases of asystole due to digitalis. I can't say that quinidine is not at all dangerous, but one must be wary of concluding that every accident that occurs while a patient is being treated with quinidine is due to that drug. With regard to the difference in efficiency between a fibrillating and a regular heart, brought out by the authors, Dr. Kirkoff at the University of Minnesota made a study of several patients with mitral stenosis and fibrillation. These patients were first digitalized until the heart rate was reduced to between 70 and 60 per minute, and cardiac output determinations were made on each patient. The

patients were then given quinidine and, after their hearts were restored to regular rhythm, cardiac output determinations were again made. The average increase in cardiac output was about 30 per cent.

DR. H. L. SMITH, Rochester, Minn.: In answering Dr. Scott's question, we meant to convey the impression that, from our experience, the administration of strychnine with quinidine renders the quinidine more effective although we have no pharmacologic proof of this belief. Dr. Margolin asked "What effect, if any, does digitalis have on patients with auricular fibrillation?" We can state that in our experience digitalis rarely, if ever, has restored normal cardiac rhythm. However, digitalis does slow the auricular rate in cases of auricular fibrillation, an effect that is very desirable. We believe that digitalis is our best cardiac medicine and we would not for a minute advise or recommend the universal substitution of quinidine for digitalis. "Is it advisable to digitalize the patient before quinidine is given?" In our experience it is not necessary to digitalize the patient before the administration of quinidine. Normal rhythm can be restored just as quickly without the use of digitalis as with it. In regard to the causes of sudden death, we agree with Dr. Weisman that the possibility of clots being detached as emboli, when the auricles assume their normal rhythm, has been greatly overemphasized. We believe that the greatest danger in giving quinidine is the occurrence of sudden death, which is probably due to depression of both the sino-auricular and auriculoventricular nodes for a sufficiently long period to produce death. In other words, the immediate cause of the death in such cases is cardiac standstill.

Clinical Notes, Suggestions and New Instruments

COLLAPSE WITH DEATH FOLLOWING THE USE OF AMPHETAMINE SULFATE

LOWELL C. SMITH, M.D., LAFAYETTE, IND.
Coroner, Tippecanoe County

During the past few years the use of amphetamine sulfate as a stimulating drug has become increasingly widespread. Severe collapse following its use has been reported, but to my knowledge no fatalities have been registered in the medical literature. The public is becoming familiar with it, and its use among students is probably more common than one would think. The following case should serve to emphasize the repeated warnings against its use in fatigue states:

REPORT OF CASE

E. J. S., a white man aged 25, while writing an examination at Purdue University Jan. 24, 1939, suddenly began to snore loudly. The professor in charge rushed to his side and with the help of several students laid him on the floor, where he continued to snore and make "funny noises" for a few minutes and then ceased to breathe. Dr. O. R. Wilson of the Purdue Health Service was called and went immediately to the classroom. The patient was apparently dead on his arrival, but Dr. Wilson in the hope of reviving him administered caffeine with sodium benzoate and epinephrine and started artificial respiration. This was continued for one hour with no other result than the expression of some gastric contents.

An autopsy was performed four and one-half hours after death by Dr. Frank P. Hunter. A complete transcript of the autopsy is given here because the conditions found are quite interesting.

The body was estimated to weigh 165 pounds (75 Kg.) and was 5 feet 8 inches (173 cm.) tall; there were good nutrition, no external markings and very little rigor.

The viscera and kidneys appeared normal except for marked epiploic congestion. The liver was very tense, smooth, blue and congested. The gastric mucosa showed marked congestion with no denuded areas. The contents consisted of food debris and bloody mucus. The stomach was markedly dilated.

The pleural cavity was slightly dry. The lungs were free except for old fibrous bands posterior to the left side. The

lungs and bronchi appeared normal. The mediastinal area was normal and the pericardial fluid was normal. The heart wall was injected, the right auricle being dilated four times its normal size. There were two thickened muscle areas anterior to the right ventricle. The coronaries were well defined. The heart valves were normal. There was no aneurysm of the aorta or other vessels.

Blood showed a dark fluid state throughout the body. There was very little coagulum in the heart only.

The skull was normal. The meningeal vessels were markedly engorged with fluid blood. There were no hemorrhagic areas. The brain and upper part of the cord appeared normal.

It was described as an anatomic death with acute splanchnic dilatation and gastric dilatation.

Dr. R. N. Harger, professor of biochemistry and toxicology at Indiana University, examined a sample of the stomach contents and reported that the sample of stomach contents weighed 0.81 ounce (23 Gm.) and consisted of a grayish white fluid. Since no tests for amphetamine sulfate suitable for analyzing material of this kind had been published, it was necessary for him to develop a test for this purpose. After considerable experimentation a test was devised which would show the presence or absence of this drug and which would give an approximate idea as to the quantity present. This test was then applied to the stomach contents. The results indicated the presence of a small trace of a substance giving the typical reaction for amphetamine. From the results obtained, Harger estimated that this sample of stomach contents contained about 0.25 mg. of amphetamine sulfate. Further tests were made for other poisons, including strychnine, but the presence of no other poison was revealed.

The results indicated that the deceased had ingested amphetamine sulfate shortly prior to his death. While the quantity of amphetamine sulfate found was very small, it of course represented only the unabsorbed drug. Since this drug is rapidly absorbed, the finding of a definite quantity in the stomach would indicate either very recent administration or the taking of a rather large dose. While amphetamine sulfate is considered a relatively safe drug, it has proved to be quite toxic in a few cases.

The student's examination paper was carefully examined and there was no indication in his writing that he had been having the slightest difficulty. Since it was a technical examination it was necessary to rely on the professor's judgment with regard to any disturbance of cerebration. After examining the answers which the patient had written, the professor stated that "the boy was writing a very good paper and had made good progress in the examination during the hour which he had written." Therefore it was concluded that this collapse came on very suddenly and without warning.

The student's room mate informed me that the patient had been making a practice of taking half an amphetamine sulfate (5 mg.) tablet half an hour before each examination but that he did not, so far as the informant knew, take any at night. During the four days prior to his death he had had about six examinations. Therefore it is probable that he had taken 30 mg. of amphetamine sulfate during the few days prior to his death, 10 mg. being taken on the day of his collapse. How much more he had taken it was not possible to determine. The twenty-five tablet bottle that he had possessed contained only ten tablets; one and one-half tablets had been given away. However, his room mate was very certain that the "brain tablets" had been in the patient's possession for a long time, "possibly a year."

All his friends agreed that the patient was a good student and had been working hard to make good grades on these examinations so that he would be placed on the honor list. He was also a good athlete and had been contemplating competing in the 220 dash in the spring. Less than a year before he passed an insurance examination and was given a preferred risk rating. There was absolutely no history of epilepsy or migraine.

COMMENT

Four important factors figure prominently in this student's death: They are a large meal, the nervous tension of the examination, fatigue and amphetamine sulfate. Probably no single one of these factors would have caused a sudden collapse

with death in a healthy person such as the patient was, but when all were present simultaneously the situation was changed. Since it is known that severe collapse can occur following the use of amphetamine sulfate in fatigue states, it is probable that it contributed to the fatal collapse in this case. The range of sensitivity to the drug is wide, and it is also possible that it may have cumulative effects. It is my belief that had the patient not been taking amphetamine sulfate he would have been able to recover his vasomotor stability when he collapsed, and this case is being reported in order that the promiscuous use and drugstore sale without a prescription of amphetamine sulfate as a "pep pill" be discouraged.

610 Columbia Street.

PULMONARY ACTINOMYCOSIS: RECOVERY AFTER THYMOL THERAPY

L. E. ETTER, M.D., AND F. L. SCHUMACHER, M.D.
PITTSBURGH

A study of the literature, with particular reference to pulmonary actinomycosis, reveals that the disease is usually fatal. It is characterized by a long, progressive course of from three months to several years. Typically, these cases progress from miliary consolidations to massive fibrosis, multiple abscesses and finally sinus formations through the chest wall.

Potassium iodide and radiation therapy have been used in the treatment, but recovery after pulmonary involvement has seldom occurred.

Myers¹ reports the successful treatment of five of his six cases of actinomycosis affecting different portions of the body. His method of oral administration of thymol was followed in the treatment of the patient here described.

Roentgenologic and bacteriologic evidence of pulmonary actinomycosis were both unquestioned in this patient. Several radiographic examinations subsequent to the institution of thymol therapy demonstrated progressive resolution of a lesion that extensively involved the right lung.

REPORT OF CASE

J. G., a teamster aged 43, became ill April 1, 1938, with a severe cough and pain in the right chest and back. Sputum was scanty at first and slightly streaked with blood.

When first seen by one of us (L. E. E.) on April 11, he was orthopneic, the respiratory rate was 40, the pulse was 106 and the temperature was 103.2 F. There was marked retardation of the respiratory excursion of the right chest, dullness over the upper portion posteriorly with distant bronchovesicular breathing and many sibilant rales. There were moist rales at the left base but no dullness. The supposition was that the patient had had a right lobar pneumonia followed by pleurisy with effusion and that an empyema had superseded it.

Treatment was symptomatic, and after one week in which there was no improvement he was hospitalized. The first roentgen examination eighteen days after onset revealed a dense thickening of the tissues over the apical and peripheral portions of the right upper lobe extending down as far as the interlobular sulcus. There were unusual visualization of the pleural margins of the sulcus and a triangular consolidation at the right hilus, the apex of the triangle extending outward into the lung parenchyma. The right diaphragm was higher than normal, and the right chest was smaller than the left with the ribs lying flatter.

Thoracentesis two days later produced 10 cc. of a straw colored fluid which, when cultured, produced staphylococci. The blood picture at this time was 4,200,000 red cells, 18,500 white cells, 82 per cent polymorphonuclears and 18 per cent lymphocytes.

The course of the disease was that of a progressive inflammatory reaction with a septic type of temperature beginning on the eighth day after admission and ranging from 99 to 103 F.

A second roentgen examination was made April 28. The lesion in the upper lobe was not greater in size—in fact, the apical portion had resumed a more normal appearance. It

bulged downward as though suspending a large amount of fluid. The hilus consolidation increased in size and reached farther toward the periphery, while the dome of the right diaphragm presented two distinct convexities. The middle lobe was entirely involved and the lower lobe remained normal.

The marked involvement of the peripleural tissues at this period, together with the decrease in the size of the lung field and the acute inflammatory reaction, suggested a probable fungous infection. Since the sputum had been negative for acid fast bacilli or other definitely pathognomonic organisms, one of us (F. L. S.) asked that search be made for the ray fungus or other fusospirochetal organisms. The ray fungus (radiating mycelia) was identified in the patient's sputum May 2 and on subsequent examination. Potassium iodide up to 50 drops three times a day was well tolerated but failed to produce any change in the physical signs at the end of eighteen days of treatment. The foul smelling sputum containing many sulfur granules increased in amount.

A roentgenogram May 3 indicated a slightly greater density in the consolidated (?) areas with a greater decrease in the size of the right chest. At the time of the patient's discharge there was the typical appearance of a lung abscess in the lower part of the upper lobe with a fluid level.

The thymol therapy as suggested by Myers was started as soon as the patient returned to his home. He was given three capsules containing 10 grains (0.65 Gm.) each in the morning with a glass of milk. The first dose caused some nausea and gastric distress but there was no vomiting. The 30 grain (2 Gm.) dose was then given for seventeen days successively in the same manner.

Immediately after the beginning of the thymol therapy there was progressive clinical improvement. Expectoration became less, dyspnea decreased. The cough stopped gradually. Temperature, pulse and respiration dropped steadily. The patient gained in weight and strength.

A roentgen examination at the office June 15 demonstrated a complete resolution of the process in the middle lobe. There was an area of only about 4 cm. in diameter in the upper lobe that seemed to be in the pleura or peripleural structures. Another examination failed to disclose any evidence of bone involvement. The right pulmonic field compared favorably with the left, although the ribs still had the flat appearance. The right diaphragm had not returned to its original shape.

A roentgenogram of the chest made in October 1938 failed to reveal any evidence of a parenchymal lesion.

COMMENT

Actinomycosis of the lungs so seldom occurs that the diagnosis is not readily made until the disease is fairly well advanced and then, probably in most cases, by exclusion.

Turner² says that the lungs are third in frequency of involvement and that the disease appears as two types, one a miliary type with the granulomatous masses along the inner lining of the bronchi, and a second type beginning at the hilus and extending into the lung parenchyma, producing the lung abscesses. These abscesses are more progressive than the usual lung abscesses seen in tuberculosis or pneumonia.

In our case the abscess cavity seen May 18 had completely disappeared after a thirty day interval. The type of onset in our case is not known, though we feel justified in saying that it probably began as a hilus type because of the dense, triangular area visualized at the right hilus at the first examination. The apical area of involvement could have been an extension—aspiration—such as Turner speaks of when he says that metastatic areas appear without adequate explanation and alternate with areas of normal tissue.

Harrison³ also speaks of the two forms of onset. Actinomycosis of the miliary type is mentioned by Sante,⁴ who says that it must be differentiated from the moderately advanced stage of the infiltrative type of tuberculosis.

In Rabin's⁵ opinion the roentgen picture is characteristic and is dependent on the fact that the disease soon extends from

the lung through the pleura and produces an intense fibrosis in the peripleural tissues. One of us (F. L. S.) saw such a case in 1926. The fibrosis of the pleura was so marked that the left pulmonic field was of a homogeneous density without displacement of the mediastinum. While attempting to aspirate, one had the sensation of passing the needle through a heavy layer of leather. The diagnosis was confirmed by bacteriologic examination of the sputum. The case terminated fatally.

In our present case the rapid resolution of the pathologic condition and the marked clinical improvement with the thymol therapy suggest that it be given a thorough trial in similar cases.

Since the foregoing article was written, one of us (F. L. S.) has seen two additional cases of pulmonary actinomycosis and one of coccidioidal granuloma. The latter is usually called California disease, and yet we find, in going over our patient's history, that his entire life has been spent in Ohio and Pennsylvania. One is inclined to forget the possibility of fungous infection, especially when dealing with a chronic lung condition. However, we believe that any case of chronic lung suppuration that presents unusual appearances should be carefully studied for evidence of fungous infection.

Suburban General Hospital.

WOOD SMOKE AS A CAUSE OF ASTHMA

BEN Z. RAPAPORT, M.D., AND RUDOLPH HECHT, M.D.
CHICAGO

M. F., a white man aged 35, had worked as a chauffeur and a telephone lineman previous to his present occupation as a fireman. He was referred to us in 1930 by the Chicago Fire Department as a suspect malingering because of his complaint of asthma after each fire. His past history was negative except for scarlet fever during childhood. No history of atopy was obtainable either in him or in his family. He had never previously had respiratory symptoms. The Chicago Fire Department informed us that there are 2,795 men employed in Chicago as firemen and that about 20,000 fires occur every year. This was the first case of asthma the department had observed that was attributable to smoke.

During the first eight months of his work as a fireman he had been to about 250 fires. Some of these were associated with severe smoke exposure, without, however, any ill effects. About eight months after being in the service he was exposed to a larger amount of smoke than in any previous fire. No ill effects were noted until three hours later, when he was awakened from a sound sleep by a feeling of tightness of the chest, wheezing and orthopnea. He was hospitalized for a week. During the latter part of this period his temperature rose to 104 F. This subsided by the end of the week. During the following week he coughed up a sputum which had a "sweet taste." Thereafter, every indoor fire which was associated with even a slight inhalation of smoke would produce asthma four hours after exposure. No discomfort was experienced during the period of exposure to the smoke, but four hours later a typical attack would start and last for from two to three days.

In January 1930, when he reported for study, he was exposed to destructive distillation of sawdust in an enclosed room for about forty-five minutes. After leaving the room his eyes were suffused and tearing but he was otherwise comfortable. The chest was examined and no wheezing was noted. At the end of two hours he complained of slight tightness of the chest, but still no wheezing was noted. At the end of four hours the attack of asthma was typical. Marked wheezing was present throughout the lungs. He was hospitalized. No relief was obtained from three doses of 1 cc. of a 1:1,000 solution of epinephrine injected subcutaneously every two hours, until it was noted that his smoke saturated clothes were alongside the bed. When these were removed and the room was aired out, the epinephrine gave him complete relief. He was well in twenty-four hours except for a slight wheeze, which continued for about a week.

From the Departments of Physiological Chemistry and Medicine of the University of Illinois College of Medicine.

He was tested by scratch as well as intracutaneous tests with wood smoke extract. The tests were negative. Acetic acid, the main product of wood distillation, was sprayed in the nose without producing symptoms.

His work was changed to that of driving a flood light fire apparatus. He has been exposed to only exceptionally large fires, where smoke has been present outdoors. He has experienced short attacks of wheezing after prolonged exposure to smoke outdoors, but he has had no actual attack of asthma following such contact.

The patient was reexamined by us in 1935. Dr. W. W. Duke,¹ who had observed a similar case, suggested that we retest the patient with wood smoke extracts, with which he supplied us. These failed to give reactions when tested intracutaneously. In addition, his throat was sprayed thoroughly with the undiluted extract, much of which he inhaled, without producing an attack of asthma.

In June 1938, eight years after he had first reported for study, he again required hospitalization for severe asthma following exposure to a fire. He had been compelled to substitute for his superior officer and enter a burning building. Four hours later, as in his previous experiences, he developed severe asthma which lasted three days. This was his first attack in eight years and his first exposure to wood smoke during this period.

COMMENT

Asthma due to inhalation of simple chemical substances has been reported. It is always problematic whether one is dealing with a primary irritant effect or whether one is dealing with true allergy. The studies of Mayer,² Curschmann³ and Gerdon⁴ on ursol (paraphenylenediamine) in fur dyes as well as their experimental work with animals seem to indicate that true respiratory allergy can occur to simple chemical substances. On the other hand, Hanzlik⁵ and others believe that the primary toxic effects of ursol are active here. Recently Romanoff⁶ has reported cases of asthma due to inhalation of sulfur dioxide. Asthma due to inhalation of dyes has also been recorded (Rackemann). Many other simple chemical substances have been incriminated as etiologic agents in asthma.

SUMMARY AND CONCLUSIONS

A fireman who has been observed for the last eight years is sensitive to wood smoke. Exposure to the smoke in a confined place is apparently necessary to precipitate a typical attack of asthma, although wheezing may occur when he is exposed to smoke outdoors. The responsible substance in wood smoke has not been determined. An attack was produced experimentally by exposure to the fumes from the destructive distillation of wood. Cutaneous tests and inhalation of wood smoke extracts gave negative results. It is interesting to note that the patient has been free from symptoms for eight years following change of occupation, with recurrence of symptoms following recent exposure.

The facts in this case which point to specific hypersensitivity are:

1. The absence of previous symptoms.
2. The eight months incubation period.
3. The recurrence of attacks with each subsequent exposure thereafter.
4. The four hour interval following exposure until the occurrence of symptoms indicates the unlikelihood of a primary irritant effect.
5. The return of symptoms on the first reexposure even years later.
6. The fact that his co-workers are unaffected by similar exposures.

EMERGENCY TREATMENT OF ACUTE HEART FAILURE

CLINICAL LECTURE AT ST. LOUIS SESSION

ALPHONSE McMAHON, M.D.

ST. LOUIS

The type of emergency treatment indicated in heart failure depends to some extent on the etiologic basis of the heart failure. The need for emergency treatment depends on the character of the pathologic process which preceded the break in compensation and on the severity of the clinical abnormality which is the expression of this particular underlying pathologic condition.

In the presence of heart failure the clinician must attempt to establish, if possible, the underlying cause and the type of failure which is present. This assumes that he is not misled by the many vagaries of cardiac rhythm which are so often misinterpreted as evidence of true failure. Inability to diagnosticate properly the cardiac state and evaluate the abnormalities of rhythm often lead to grave mistakes in diagnosis, resulting in many cases in unending psychologic turmoil in the patient who has been exposed to the incorrect diagnosis. Cardiac neuroses that may serve to incapacitate a patient are often born of the fear which arises from the false diagnosis of "heart trouble."

In emergency cardiac states it may not be possible to determine the underlying cause. In such conditions the emergency treatment must be instituted which is indicated by the evident clinical manifestations. Such treatment must needs be prompt to be life saving. However, when the time permits, a brief history of the condition may be obtained from the patient or his relatives. Valuable information as to the possible underlying clinical factors responsible for the acute attack may be obtained in the history. Much of value regarding the existence and progression of preceding cardiac or cardiovascular factors may be learned by well chosen questions. Such apparently simple facts as those detailing the onset and progress of the acute attack may give information of inestimable value with specific clues as to the required treatment.

The physical examination of the heart in cardiac failure is a *sine qua non* of diagnosis. Such important facts as the rate, rhythm and character of the heart sounds should be carefully noted. Disturbances of mechanism indicating heart block, auricular fibrillation or flutter may be evident and extremely valuable in determining causation of failure and in indicating treatment. When possible, a general examination of the patient should be conducted with particular regard to other signs of cardiac failure such as orthopnea, enlarged liver, ascites and peripheral edema or anasarca.

For the purpose of classification, acute cardiac failure may be grouped into that associated with the infectious diseases such as pneumonia, diphtheria, sepsis and that occurring in the course of thyrotoxicosis, syphilis, arteriosclerosis, hypertension and rheumatic heart disease. The clinical cardiac manifestations in the latter diseases may be protean, seldom conforming to a constant pattern and hence seldom of themselves indicative of the underlying pathologic condition.

The provoking causes of heart failure are multiple. Acute infections sometimes mild in character, such as a grippal or a respiratory infection, may serve to initiate a break in compensation in a heart previously diseased but well compensated. Recurrent rheumatic infections may undermine the integrity of the heart muscle, as will repeated carditis with tonsillitis occurring regularly once or twice a year. Arrhythmias are often the determining causes of acute cardiac failure. The postoperative cardiac failure is often transient and may be associated with pulmonary embolism. Extensive embolism may result in immediate death. Extreme emotional states, excitement, grief or sorrow may play significant roles in the causation of cardiac failure.

The acute heart failure of the infectious diseases may respond to emergency treatment, but since it occurs after severe and prolonged toxemia the response to treatment may be unsatisfactory. The most important fact in the therapy of this type of cardiac disturbance is concerned with the prevention of serious cardiac accidents. This may be effected by the exercise of proper care of the patient by the physician during the acute illness. The heart should be carefully watched during the acute stages of the disease so that, when signs of failure appear, proper therapy may be instituted early. Prevention of cardiac disability in the infectious diseases is far more important than the treatment of the cardiac emergency.

In the diagnosis and evaluation of cardiac states associated with failure, it may be well to mention some clinical conditions which, in the intensity of the cardiac manifestations, may simulate acute cardiac failure. Chief among these is pulmonary embolism with infarct, presenting a symptom complex that closely simulates coronary thrombosis with many of the dramatic phases of the latter condition. Cardiac deterioration in pulmonary infarct may be rapid and startling. The symptomatology of pulmonary embolism bears so striking a resemblance to that of coronary thrombosis that it may be differentiated only by means of the electrocardiogram. Sufficient time must elapse to produce diagnostic changes adequate to assist in the solution of this difficult problem.

Other conditions which may cause difficulties in diagnosis are spontaneous pneumothorax inducing severe cardiorespiratory symptoms, massive collapse or atelectasis producing a clinical picture often confused with true heart disease because of the respiratory difficulty and pleural effusion. The last named condition is often characterized by a slowly developing dyspnea chiefly on exertion, closely simulating heart failure.

SYMPTOMS AND SIGNS

The symptoms and signs of cardiac failure may be grouped for purposes of convenience into those occurring with left ventricular failure and those occurring with right ventricular failure. In left ventricular failure, cardiac asthma or paroxysmal dyspnea with edema of the lungs is a frequent sign alone or with Cheyne-Stokes respiration. These will be discussed later at greater length. The cardiac rhythm in this type of failure may be of the gallop type, or any of the arrhythmias may be present. Pulmonary congestion is frequent and in this condition the x-rays may aid in diagnosis. Vital capacity is reduced to as low as 60 per cent of normal while circulation tests reveal a prolonged decholin time with a normal ether time.

In the right ventricular failure, dyspnea is likewise common but it is more apt to be of the simple type.

From the Department of Medicine, St. Louis University School of Medicine.

Read in the General Scientific Meetings at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 15, 1939.

The liver is, as a rule, enlarged and may be tender and pulsating. Hydrothorax, frequently unilateral, is common. With dilatation of the right ventricle and right auricle, a dullness to percussion may be elicited at the lower end of the sternum. This may also be determined by means of x-ray examination. Generalized edema with marked gain in weight may be present early in the failure. A gradual unexplained weight gain may be the forerunner of a break in compensation. Jaundice is not uncommon. The finding of albumin and erythrocytes in the urine indicates the existence of a renal congestion. Special tests of the circulation reveal an increased venous pressure together with a prolongation of the ether time. Prolonged ether and decholin time indicate a failure of both right and left ventricles.

In addition to the foregoing symptoms and signs of cardiac failure, others of variable frequency and significance may be added. The following may serve to aid in the diagnosis of the underlying pathologic condition producing the failure:

1. Pallor may be present more frequently than cyanosis.
2. Precordial discomfort may or may not be present. When present and related to exercise, it may have a definite significance.
3. Palpitation is frequently present without a clue as to the underlying associated rhythm.
4. Tachycardia is common but bradycardia may occur at times with disturbance of the sinus node or the bundle of His.
5. Heart measurements may be greater than normal as evidence of hypertrophy or dilatation in true heart disease.
6. Heart sounds may be variable in character. They are usually weak; they may be irregular. The type of arrhythmia must be determined. Murmurs vary with the type of disease. A systolic murmur at the apex is most frequent.
7. Gallop rhythm, as mentioned, is common. Heart block may appear with involvement of the conduction system.
8. Lungs may show evidence of basal congestion with rales and impaired resonance. Dullness may be found when fluid is present in the pleural cavity. The respiratory rate is usually increased.
9. Fever and leukocytosis may coexist with infectious processes. Both are found consistently with coronary thrombosis.

DYSPNEA

Among the premonitory symptoms of heart failure, dyspnea stands out preeminently. Dyspnea may of itself serve to call attention to an impending heart failure. It may manifest itself as the simple or exercise type, evident on moderately strenuous exertion such as walking fast or climbing stairs. It may or may not be accompanied by a sensation of precordial pressure or pain. Cardiac palpitation is a common associate of the exercise, dyspnea disappearing with rest. Such a complex symptomatology may be present for months before more evident signs of failure appear.

A second form of dyspnea may occur as a paroxysmal or nocturnal dyspnea, sometimes termed cardiac asthma. Accompanying this is a pulmonary edema present in varying degrees. The onset of the attack is as a rule sudden, occurring during sleep or after some exertion such as coughing. The patient often awakens gasping for breath and conscious of the rapid heart action. Precordial pain is frequently present and sweating is a distressing symptom. Cough with varying amounts of sputum is present with edema. The attack is at times accompanied and aggravated by severe fright.

The mechanism of the attacks is probably an acute left ventricular failure following sudden elevation of blood pressure occurring during sleep as a result of exciting dreams, urinary bladder discomfort or other sensory stimuli. This is the so-called "back-pressure

theory" in which a pulmonary congestion occurs. Other suggested explanations have been the "nerve theory" which presupposes an alteration in the nervous control of the bronchial musculature and the theory of "failure of forward pressure" with consequent accumulation of acid substances in the tissues.

A third type of dyspnea which is important, extremely distressing and often unrecognized as a sign of cardiac failure is the Cheyne-Stokes respiration. This type of dyspnea occurs frequently in heart disease, being found most often in arteriosclerotic and hypertensive states. It may be an index of left ventricular failure in these two conditions. The duration of the periods of apnea varies from ten to forty seconds. The apnea is more disturbing when nocturnal. The patient often awakens during the long periods of apnea to find himself struggling for breath. The fear induced by this attack prevents sleep and so the element of prolonged exhaustion is added to the already embarrassed myocardium, further reducing the cardiac reserve.

The foregoing forms of dyspnea, from the simplest or exercise type to the most complex, may be valuable in determining the extent and severity of cardiac disability. Immediate understanding of the significance of this symptom, particularly in its more serious manifestations, the nocturnal dyspnea with pulmonary edema and the Cheyne-Stokes respiration will result in prompt and adequate therapy with the consequent restoration of cardiac integrity.

The essential treatment of cardiac failure depends, as has been said, on the factors underlying the failure and also on the clinical expressions of the failure. It is necessary then, in any failure, to determine whether the heart action is arrhythmic or rhythmic and whether or not edema exists. The location of the edema, whether general or pulmonary, may be of great importance.

If the heart is arrhythmic, the character of the arrhythmia should be determined, instrumental aids being used for more accurate determination when possible. An electrocardiogram may reveal not only the arrhythmia but also the character of any underlying myocardial changes.

GENERAL PRINCIPLES OF TREATMENT

With the foregoing differentiations and clinical determinations in mind, one may proceed to the consideration of certain general principles of treatment as applied to acute cardiac failure:

1. Rest in bed should be absolute. It presupposes adequate and proper nursing care. In simple congestive heart failure with normal rhythm, rest in bed may be modified to prevent formation of venous thrombi, which may develop as a result of the marked slowing of the circulation.
2. Sedation should be obtained by morphine given subcutaneously or intravenously in adequate doses. In the acute stages of heart failure, rest is most important. Dilaudid hydrochloride may be used in doses of $\frac{1}{64}$ to $\frac{1}{32}$ grain (from 1 to 2 mg.). Respiratory depression may be controlled by using caffeine, atropine or a respiratory stimulant such as lobeline or coramine. Barbiturates may well serve the purpose.
3. When cardiac failure is accompanied by arrhythmia, the tachycardia should be treated and for this purpose digitalis or quinidine should be used in adequate doses. When sinus rhythm is present with cardiac failure the effect of absolute rest in restoring cardiac integrity may be determined before digitalis is used. Digitalis has its most pronounced effect in cardiac failure. In circulatory failure the effect of digitalis is less pronounced and may even be negative.

When auricular fibrillation or auricular flutter exists, digitalis should be used in large and adequate doses. In the former condition quinidine may be of value in restoring

ing rhythm. When the arrhythmia is due to auricular or ventricular paroxysmal tachycardia, quinidine is usually of greater value. In the latter condition digitalis may prove to be dangerous by converting the tachycardia to ventricular flutter or fibrillation.

What may be expected from the use of digitalis in cardiac failure due to the various underlying causes? In auricular fibrillation accompanying mitral stenosis, arteriosclerotic or thyroid heart disease the results following its use may be excellent. In thyroid heart disease the effect is usually less satisfactory than in the two preceding conditions. In mitral stenosis with sinus rhythm the results with digitalis are, as a rule, not as good as when fibrillation is present. In hypertensive and arteriosclerotic heart disease with failure and sinus rhythm a good result may be obtained. Aortic insufficiency with failure shows but little result from the use of digitalis.

The method of dosage of digitalis varies with the urgency of the condition to be treated. Hence digitalization may be accomplished slowly or rapidly. Oral administration of the drug is the method of choice and can be used when the stomach will tolerate the drug. When a gastric upset renders this route impossible of use, other routes of administration may be employed such as the intramuscular, the intravenous or the rectal route. In oral administration, the dosage and the rapidity of administration will depend on the severity of the failure. Where the urgency of the case demands rapid digitalization, the total dosage of 15 cc. or 22½ grains may be given orally in three equal doses within eight, twelve or twenty-four hours.

The dosage of digitalis when administered either intravenously or intramuscularly will likewise vary as it does with the oral administration. A dose of 2 cc. twice daily will usually suffice to restore compensation.

The drug may be administered rectally in the form of suppositories, as an infusion or as the fat-free tincture. The strength of the infusion is usually from 15 to 22 grains (1 to 1.4 Gm.) of the powdered leaf in 60 cc. of water. Of this, 30 cc. is given morning and evening. The fat-free tincture may be given in doses of 40 minims (2.5 cc.) twice a day. In severe auricular flutter this dose may be increased to 60 minims (4 cc.) twice a day.

A fact of great importance during the process of digitalization is the incidental occurrence of nausea and vomiting or the persistence of these symptoms, present before using digitalis. These are often falsely interpreted as signs of digitalis intoxication. The failure to understand properly and evaluate these symptoms, which are due to the congestive failure frequently, results in a catastrophe because of the discontinuance of the digitalis before adequate digitalization has been obtained. Definite signs of digitalis toxemia such as pulsus bigeminus, premature beats or the electrocardiographic signs of overdigitalization should be present before one discontinues the drug in the presence of gastric symptoms.

Digitalis may be dangerous when used in conduction disorders and in coronary sclerosis with a high degree of block. In the latter condition it may set up a ventricular fibrillation.

Strophanthin (crystalline ouabain) may be used in acute failure with or without generalized edema in cases in which digitalis has not been given for at least three days. The dose of 0.0003 Gm. (½₂₀₀ grain) is given intravenously and repeated in twelve hours. Subsequent doses may be given at twenty-four hour intervals. It

may have some value in cases of gallop rhythm with failure. Here it may be given in two daily doses combined with theophylline with ethylene diamine (aminophyllin) or mercupurin.

Diuretics have their most important use in the treatment of subacute or chronic congestive heart failure. However, they may prove to be valuable in restoring compensation in acute failure by prompt reduction of blood volume with rapid and increased diuresis, thus removing one source of ventricular strain. The diuretics most frequently used are the xanthine derivatives and the mercury compounds.

Of the former group the most common are theobromine, with sodium salicylate, theobromine with calcium salicylate, theophylline, theocin, theophylline with ethylene diamine or aminophyllin. The last named is used orally, rectally or intravenously. When given intravenously with dextrose, from 10 to 20 per cent in amounts of from 50 to 500 cc., it serves as an excellent diuretic. The intravenous dosage of the drug varies from 3 to 7½ grains (0.2 to 0.5 Gm.). It may be given twice a day, the frequency of dosage and amount of the drug being governed by the existing condition.

The mercurial diuretics most commonly used are mercupurin, salyrgan and novasurol. The last named, being more toxic than the two preceding, is seldom used. There is little choice between the first two drugs either as to effect or as to tolerability. The former of the two may be slightly less irritating to kidney tissue. These diuretics may be used in the presence of acute congestive failure and the diuresis may be immediate and effective. They may be given intramuscularly, intravenously, rectally as suppositories and intraperitoneally diluted with ascitic fluid. The dose varies from 0.5 to 2 cc. and the administration may be daily or every three to five days depending on the severity of the condition and the result obtained with a given dose.

I have discussed the symptoms of paroxysmal dyspnea as evidence of acute left ventricular failure. Since this condition may at times be extreme, it is possible that one may be obliged to regard it as of such severity as to require immediate and urgent treatment. In that case morphine should be given in adequate doses to produce complete relaxation. Any respiratory depression following the use of this drug may be combated by the drugs mentioned. Venesection with the removal of from 400 to 500 cc. of blood may produce striking immediate results when pulmonary congestion is severe. Strophanthin intravenously may be given with the usual precaution relative to the antecedent use of digitalis. Dextrose in a concentration of from 25 to 50 per cent and in amounts of 50 cc. may be given intravenously with or without aminophyllin. The latter is of value in arteriosclerotic and hypertensive heart failure. Ligation of the lower extremities may be of value by reducing the volume of blood flowing to the heart. Mercurial diuretics may be given at the time of the attack. When these are given nightly for a few consecutive nights they may quiet the nocturnal attacks occurring in aortic regurgitation of syphilitic origin.

Glycerol trinitrate may be of value. Oxygen inhalations usually are of definite benefit. The concentration of the oxygen may be from 50 to 90 per cent with a flow of from 4 to 6 liters a minute. Caffeine with sodium benzoate from 1 to 3 grains (0.06 to 0.2 Gm.) may be given intramuscularly or subcutaneously every three to four hours.

The distressing nocturnal symptoms accompanying the apneic intervals occurring in Cheyne-Stokes respira-

tion may be relieved by the intravenous use of aminophyllin twice daily in doses of $7\frac{1}{2}$ grains (0.5 Gm.). This may be given in water, saline solution or dextrose solution. It should be given slowly. The determination of the possibility of the Cheyne-Stokes respiration as the factor responsible for the nocturnal dyspnea may be made by using a test dose of 5 grains (0.3 Gm.) of aminophyllin given rectally by suppository. If relief is obtained by this means the active intravenous treatment as mentioned before may be instituted.

Acute heart failure may supervene in clinical conditions other than those so far considered. It may not present evidence of congestive failure. In heart block and the accompanying Stokes-Adams syndrome ventricular standstill may be followed by syncopal attacks and even convulsive seizures. The treatment of the ventricular standstill is designed to effect restoration of normal ventricular function and hence must be specific for that purpose. Epinephrine hydrochloride may be given intracardially in doses of 1 cc. in 1 : 1,000 solution. This treatment may likewise be effective in post-anesthetic ventricular standstill. The technic of this injection is simple. A lumbar puncture needle is used and the needle is inserted into the heart through the fourth left intercostal space 2.5 cm. to the left of the left sternal border. Subcutaneous injections of the same drug in from 0.3 to 0.6 cc. doses may be given at frequent intervals as often as every two hours. As much as 1 cc. of the drug may be injected at two hour intervals without distressing constitutional symptoms. The drug should be avoided in ventricular tachycardia or fibrillation. Atropine sulfate in doses of from one-twentieth to one-twelfth grain (0.003 to 0.005 Gm.) may be given subcutaneously. Ephedrine sulfate may be of value and is given orally in doses of from three-eighths to one-half grain (0.024 to 0.032 Gm.) from three to four times a day. Barium chloride is used to increase ventricular irritability and is given in one-half grain (0.03 Gm.) doses three times a day. Digitalis and quinidine should be used only when acute failure supervenes.

Coronary thrombosis with extensive cardiac infarction may result in immediate death from cardiac failure. When this eventuality does not supervene, the cardiac manifestations may be severe and if not properly treated may terminate in failure. The general reaction to the thrombosis may be striking with all the signs of severe shock, including sudden reduction of blood pressure, tachycardia and interference with cardiac and peripheral circulation. The mechanism of the heart may be regular or irregular. When irregular, various types of arrhythmias may be present. The arrhythmias most apt to be present are paroxysmal ventricular tachycardia, ventricular fibrillation, auricular fibrillation, auricular flutter, bundle branch block, usually transitory, and auricular-ventricular block. This may be complete and, when so, usually indicates an involvement of the right coronary artery with posterior infarction.

The sequelae of this coronary accident may be striking and may appear separately or as steps in a gradually progressive condition. The most common of these sequelae are edema of the lungs, sudden cardiac failure, shock persisting to the second and third days with an unresponsive low systolic blood pressure, embolism either pulmonary or peripheral following the formation of mural thrombi at the site of the infarct, rupture of the heart muscle that may be partial and nonfatal, and lastly cardiac aneurysm, which may be diagnosed by means of the fluoroscope.

The treatment of the acute coronary thrombosis, with which acute cardiac failure is always potentially associated, consists of rest, which must be immediate and absolute. Morphine should be used in large doses for relief of pain. It may be given intravenously if necessary to relieve severe pain and to secure rest. Vasodilators should be used and for this purpose theobromine with sodium salicylate (diuretin) or aminophyllin is most effective. The latter may be given intravenously in a dose of $7\frac{1}{2}$ grains (0.5 Gm.). Glyceryl trinitrate should be avoided except when the systolic blood pressure is unusually high and when more rapid reduction of blood pressure is desired.

Strophanthin, to be given intravenously during the attack, is recommended by some foreign observers. Its use does not seem to be justified in the absence of cardiac failure. The existence of cardiac failure should likewise be the indication for the use of digitalis. The latter drug may be dangerous, as has been mentioned, when used in the presence of a high degree of heart block. Quinidine should be used when multiple extrasystoles appear. It may be used in a dose of 3 grains (0.2 Gm.) four times a day. Its use may prevent the development of paroxysmal ventricular tachycardia and ventricular fibrillation. The dose may be increased to 60 grains (4 Gm.) daily if needed to prevent the development of the latter condition. Oxygen inhalations may be of value in the first twelve hours after the attack.

It is not possible, in a limited presentation of this type, to discuss all the cardiac conditions that may result in failure. At best only general principles of therapeutic procedure can be discussed. Many of the cardiac arrhythmias, when severe, produce an appearance of failure and, in fact, with persistence of the arrhythmia may actually result in cardiac failure. Of these, perhaps the most common are auricular paroxysmal tachycardia and ventricular paroxysmal tachycardia. The former may be identified by the character of the onset and the cessation of the attack, which is typical. Treatment in the transient attacks seldom need be applied. In the more prolonged attacks, however, cardiac failure may supervene and so it may be advisable to restore normal rhythm as quickly as possible. For this purpose vagal or ocular pressure may be applied. Emetics may be of value. More recently acetyl- β -methylcholine chloride has been used in doses of from 10 to 50 mg. It is injected subcutaneously and has given good results. Quinidine in doses of 6 grains (0.4 Gm.) every two to four hours for five doses gives good results in selected cases. The use of digitalis to sensitize the vagus in the recurrent cases has many adherents.

Ventricular paroxysmal tachycardia is a far more potentially dangerous arrhythmia than the preceding because of the possibility of its transition into ventricular fibrillation or flutter. The attack is often ushered in by frequent runs of extrasystoles; clinically it may be indistinguishable from the auricular type. Quinidine in adequate doses, as much as 60 grains (4 Gm.) a day in divided doses, should be given at once. Digitalis, as has been said, may convert the condition into the more dangerous ventricular fibrillation.

CONCLUSION

A recapitulation may be made of some of the more important points mentioned in the emergency treatment of heart failure. Most important of all these points is the necessity for proper diagnosis of the type of existing heart failure. This should be arrived at by a history, physical examination and other diagnostic aids when

possible. The diagnosis of the underlying pathologic state of the heart and its clinical expression will determine the indications for the type of treatment to be instituted.

It is well to remember that it is not possible to group all cases of cardiac failure together and so to institute one type of treatment. Not all cases of acute failure require digitalis; in fact, in some cases the use of this drug may be dangerous. When the drug is required it should be given in adequate doses with the hope of restoring cardiac compensation as quickly as possible.

Adjuvants, such as rest and diuretics, should be used as indicated. One fact should stand out above all others: that is, one should not cease treating acute heart failure because of apparent lack of response, for restoration of the heart muscle to a compensated state is often obtained when least expected.

The treatment of paralyzed muscles of the flaccid type has been based chiefly on clinical experience. The measures commonly employed are electrical stimulation, massage and passive movement, heat, rest and muscle reeducation. The exact indications for the use of these procedures alone or in combination, however, are still a subject of controversy. Thus, in the treatment of poliomyelitis many clinicians claim that electrical stimulation is contraindicated especially in the early stage of paralysis. They advocate rest. Others stressing the rapid rate of atrophy and degeneration maintain that something should be done to prevent, so far as possible, the progress of atrophy and fibrosis. They decry rest and advocate light massage and passive movement to be followed later by electrical stimulation. A review of the literature reveals considerable confusion and disagreement regarding the value of these measures, with their indications and contraindications.

In view of the need for more precise knowledge as to the actual effects of the commonly used physical therapeutic measures, a series of animal experiments has been undertaken. *Macacus rhesus* monkeys were

used. In the first group of experiments an attempt was made to study the effects of treatment on the course of atrophy and degeneration of denervated muscles. In the second series, treatment was carried out for longer periods of time with a view toward studying the effects on regeneration and restoration of the paralyzed muscles and their nerves.

In the treatment of the lower motor neuron type of paralysis the chief principles of therapy have been based on the concept that inactivity is responsible for the atrophy. The fact that denervated muscle continues to respond to the galvanic current has been utilized in the treatment of flaccid paralysis. By stimulating the paralyzed muscles with the galvanic current an artificial stimulus is substituted for the normal voluntary impulse.

The earliest experimental works on this problem were those of Reid¹ and Brown-Séquard² on frogs and rabbits. They reported that daily electrical stimulation prevented atrophy of muscles paralyzed by nerve section. This idea held sway until 1915, when Langley³ and his associates repeated the experiment on rabbits and found that wasting of the paralyzed muscles progresses despite daily stimulation by the galvanic current.

Does daily electrical stimulation prevent muscle atrophy? In the first experiment of the present investigation the gastrocnemius-soleus muscles were paralyzed by sectioning the sciatic nerve in both lower extremities of two monkeys. The severance was made at the level of the great trochanter. The extremities were kept in protective plaster of paris casts, which were removable. The muscles of the left side were treated by galvanic stimulation, ten good contractions being given daily, the treatment beginning on the day following the operation. The paralyzed muscles of the right lower extremity received no treatment. At the end of six weeks the gastrocnemius-soleus muscles were removed in toto from both extremities and immediately weighed. The results may be seen in table 1.

The treated muscles showed slightly more wasting than the untreated. One may question the validity of comparing the same muscle groups of opposite extremities. Our experience with a very large number of monkeys has assured us that the normal variation in weight of the same muscle groups in opposite extremities is very slight. This has been found to be true also in rabbits by Lipshutz and Audova.⁴

In the second experiment three groups of monkeys in which one sciatic nerve was sectioned and sutured were treated as follows: One group received daily electrical stimulation (ten good contractions by galvanic current), another daily massage and passive movement, and the third group complete rest by immobilization in a cast. The opposite extremity served as the control in each animal. The paralyzed extremity was placed in a removable protective plaster cast in all groups. Treatment was not begun until two weeks after the nerve section, during which period the paralyzed muscles were kept at rest in a neutral position in their protective casts. At the end of four weeks of treatment (six weeks after nerve section) the gastrocnemius-soleus muscles were removed and the amount of atrophy was determined by comparing the weight

From the Departments of Nervous and Mental Diseases, Anatomy and Physical Therapy, Northwestern University Medical School, and Department of Neurosurgery (Dr. Cleveland), Marquette University.

of the paralyzed muscles with that of the normal control side. The results may be seen in table 2.

The amount of atrophy was practically the same in the three groups. We may conclude, therefore, that muscle atrophy following nerve section in the *Macacus rhesus* monkey progresses up to a period of at least six weeks despite treatment by electrical stimulation, by passive movement and massage or by complete rest. It should be emphasized that these observations deal only with the amount of atrophy. It may be mentioned at this time that demonstration of atrophy in terms of wasting of muscle is not an accurate guide to the severity of the lesion. The qualitative changes occurring in the muscle fibers, intramuscular nerves and blood vessels must be evaluated. The degree of muscle degeneration and fibrosis and the amount of functionally preserved muscle fibers are the important determinants of the future restoration of the muscle when reinnervated.

What are the effects of treatment on the regeneration and restoration of muscles? The following experiments were carried out to compare the effects of electrical stimulation, of massage and passive movement and of immobilization, maintained for a period of time long enough to permit regeneration of the nerve to the paralyzed muscles. Four groups of animals were used in this experiment. In each monkey the right sciatic nerve was severed and sutured immediately. Removable plaster of paris casts were applied to the paralyzed extremity for protection and also to serve as a splint for the denervated gastrocnemius-soleus muscles. A period of four weeks of rest was allowed before active treatment was begun. One group received daily electrical stimulation (ten contractions, galvanic current), another group received daily massage and passive movement, a third group received the combination treatment of daily electrical stimulation and

was longer (five months). Treatment was begun after four weeks rest, during which time the paralyzed muscles were splinted and protected in a plaster cast.

A final experiment was conducted, treatment being started immediately following nerve section and suture

	35	4.90	12.09	7.19	58.7

without allowing a rest period of four weeks before beginning treatment, as was the condition in the previous two experiments. An additional group of animals was included, these monkeys receiving no supervised treatment whatever following the nerve section and suture. They were kept in cages during the six months course of the experiment and were examined weekly as to the appearance of voluntary movement and return of faradic response. The treatment period in this experiment was for six months. All casts were removed at the end of five months so as to permit active movements of the recovering muscles. The results may be seen in table 5.

The results of this experiment are in accord with the two previous ones. The best restoration of muscle bulk was obtained in two groups, one of which received massage and passive movement therapy and the other no supervised treatment. The poorest response was in the group of animals immobilized in plaster casts with no additional treatment.

COMMENT

Our studies indicate that atrophy and degeneration of denervated skeletal muscle are just as inevitable as are the changes which occur in the peripheral portion of a severed nerve. We have shown that no form of physical therapy prevents atrophy up to a period of six weeks.

From a clinical point of view, atrophy has been the feature receiving most attention by many in dealing with paralyzed muscles of the flaccid type. As already noted, the qualitative changes in the paralyzed muscles, rather than the quantitative loss of bulk, determines in great measure the type of response to therapy that can be expected when the regenerated nerve again

TABLE 1 (Experiment A).—Immediate Treatment by Electrical Stimulation (Galvanic Current, Ten Contractions Daily)

Sciatic nerve sectioned bilaterally and sutured immediately.
Period of treatment six weeks.

also massage and passive movement, and the fourth group was kept immobilized in the plaster cast in a state of continuous and prolonged rest. After two months of treatment (three months following nerve section and suture) the gastrocnemius-soleus muscles were removed and weighed. The results are seen in table 3.

A similar experiment was carried out on another group of animals; the period of treatment, however,

ATROPHY OF MUSCLES—CHOR ET AL.

1031

innervates the paralyzed muscle. Microscopic studies show that, associated with atrophy and degeneration of denervated muscle, reparative and regenerative phenomena go hand in hand. The striking increase in sarcolemmal and muscle nuclei is the first evidence of this reaction. After the degeneration of the muscle cells, however, fibrosis soon follows. This response of fibrous tissue cells, derived in part from the sarcolemmal nuclei and from the degenerated muscle, occurs insidiously. Microscopic studies show that by six weeks,

TABLE 5 (Experiment E).—Six Months' Treatment; No Preliminary Rest

Treatment	Mon- key No.	Weight Paralyzed Muscles, Gm.	Weight Control Muscles, Gm.	Differ- ence, Gm.	Atrophy, %

	45	29.71	45.52	15.81	34.73

at which time there is evidence of longitudinal splitting within the degenerating muscle fibers, fibrosis makes its appearance. It is not prominent, however, until the later stages. The excessive invasion of the damaged muscle by fibrous tissue not only replaces the muscle fibers which have undergone degeneration but also exerts a damaging effect on the remaining parenchyma by compression and "cirrhosis." Excessive fibrosis interferes

It may be seen from the present experiments that each type of therapy resulted in a rather clearcut response on the part of the regenerating muscle. In experiment D, the best restoration of muscle bulk occurred in the group of animals which received massage and passive movement therapy. A recovery of 81.4 per cent (18.6 per cent atrophy) and 89.5 per cent (10.5 per cent atrophy) after six months clearly supports this conclusion. In experiment E it may be noted that the best results were obtained in two groups, one receiving massage and passive movement and the other receiving "no treatment." In each instance a recovery of approximately 65 per cent (35 per cent atrophy) was obtained. It should be noted that the group which received "no treatment" were kept in small cages which minimized stretching of the paralyzed muscle and yet permitted some degree of motion equivalent to passive movement.

The poorest results were obtained in those animals in which the paralyzed limb was kept in complete and prolonged immobilization by means of a plaster cast. This was a constant finding in all the experiments. Its explanation is obvious. Grossly there was marked fibrosis and ankylosis at the ankle and knee joints. The gastrocnemius-soleus muscles were surrounded by thickened septums of fibrous tissue, and throughout the pale muscles were whitish and yellowish streaks—cords of dense fibrous tissue. Microscopically this fibrosis was clearly demonstrable both surrounding and within the muscle fibers. Such a state of "cirrhosis" of the muscle hinders the restorative process. The results of therapy by electrical stimulation suggest that this form of treatment does not give as good a restoration of the bulk of regenerating muscle as may be obtained by massage and passive movement. Further studies correlating the restoration of muscle

TABLE 6.—Correlation of Muscle Restoration with Nerve Regeneration Three Months After Sciatic Nerve Section and Suture (4 Weeks Rest in Cast Before Beginning Treatment)

Treatment	Monkey No.	Muscle Atrophy	Regenerated Sciatic Nerve Fibers	Regenerated Branches to Gastrocnemius- Soleus Muscles	Maturity of Fibers	Return of Voluntary Movement (No. of Days)	Return of Faradic Response (No. of Days)

with the circulation in the muscle and also retards the regeneration of muscle fibers. Since muscle regenerates by outgrowth from the healthy stumps of partially degenerated muscle cells, the importance of preserving the parenchyma is obvious. It is commonly emphasized throughout the literature on the treatment of flaccid paralysis that the condition of the remaining muscle is the important factor in determining the degree of muscle repair and recovery which follows the regeneration of the peripheral nerve. The process of muscle atrophy and degeneration, however, progresses despite attempts at early therapy. Treatment does influence the quality of the denervated muscle (1) by aiding the circulation and (2) by minimizing fibrosis.

bulk with muscle function are needed in order to establish more definitely the effects of these therapeutic measures.

A noteworthy finding was the uniformly better results obtained in the animals which were permitted a preliminary period of rest of four weeks (the paralyzed muscles supported in a neutral position by plaster casts) before treatment was instituted. The results support the clinical impression that rest is indicated in the early stage of lower motor neuron paralysis.

CORRELATION OF MUSCLE RESTORATION WITH NERVE REGENERATION

A study of the regenerated nerves to the gastrocnemius-soleus muscles was made to determine whether or not there is any correlation between regeneration of muscle and regeneration of nerve. It was found that

at the end of three months 60 per cent of the normal number of fibers of the sciatic nerve made their appearance in the regenerating distal portion.⁶ Of these there were twice as many unmyelinated as myelinated fibers. In table 6 the number of regenerated nerve fibers are listed along with the percentage of atrophy of the gas-

TABLE 7.—Correlation of Muscle Restoration with Nerve Regeneration

Six months after sciatic nerve section and suture (four weeks rest before treatment)

Treatment	Mon-key	Atrophy	Regenerated Sciatic Nerve Fibers		Return of Voluntary Movement (No. of Days)	Return of Faradic Response (No. of Days)
			Total	Myelinated		
Electrical stimulation	29	59%	69,000	22,000	158	152
	30	31%	76,000	33,500	158	152
	31	44%	33,000	103	152

	33	19%	90,000	36,000	76	87
Immobilization	34	61%	85,000	19,000	None	None
	35	59%	102,000	28,000	None	None
			Average 84,000			
Total fibers in normal sciatic, 100,000; myelinated, 35,000.						

trocnemius-soleus muscles grouped according to the type of physical therapy employed.

The total number of regenerated fibers in the distal portion of the operated sciatic nerve varied between 51,000 and 94,000, with an average of approximately 60,000. In monkey 25, in which the best restoration of muscle occurred, 24 per cent atrophy, there were 65,000 regenerated fibers, whereas in monkey 23, in which the poorest restoration occurred, 65 per cent atrophy, there were 60,000 regenerated fibers. There appears to be no definite correlation between the total number of regenerated fibers of the sciatic nerve and restoration of the gastrocnemius-soleus muscles. The number of myelinated fibers in the regenerated nerve was fairly constant throughout the series and it may be concluded that the degree of myelination of the fibers likewise is not directly related to the restoration of muscle.

The total number of regenerated fibers in the branches of the nerve going directly to the gastrocnemius muscles varied from 4,287 to 10,000. Here also there is no correlation between nerve regeneration and muscle restoration.

After six months the number of regenerated nerve fibers reaches 80 per cent of the normal.⁷ Therefore, three times as many regrew in the first three months period as the number added during the second three months period. The process of myelination seems to keep pace with the regrowth of axis cylinders. In table 7 the number of regenerated sciatic nerve fibers found six months after nerve section and suture is compared with the restoration of muscle in each instance.

The number of regenerated fibers in the sciatic nerve varied between 69,000 and 102,000, with an average of approximately 84,000. There is no direct correlation between the number of regenerated fibers and the restoration of muscle. The number of myelinated fibers was approximately one third of the total—the same ratio found after three months' regeneration. In this series the poorest myelination occurred in monkey 34, in which the poorest restoration of muscle was

found. In the monkeys with good muscle recovery, myelination of the regenerative fibers was correspondingly good.

In the third group of monkeys, nerve fiber counts were made of the regenerated branches to the gastrocnemius muscles. A considerable variation in total number of fibers was found. This is true also in the normal, in which the total number of fibers varied from 11,000 to 21,000. In this group there is no definite correlation between the number of regenerated nerve fibers and restoration of muscle, but it would appear that for regeneration of muscle a minimal number of regenerated nerve fibers must be present.

There was considerable variation in the number of days following nerve section and suture at which voluntary movement returned. In each experiment the earliest recovery was found in those animals which received massage and passive exercise. The poorest functional recovery was in the animals treated by prolonged immobilization in plaster casts. The fibrosis in the muscle and about the joints and ligaments may interfere with movement of the muscle despite the apparently good regeneration of the nerve. The return of motor function was found to vary considerably, as early as fifty-five days in monkey 24 and as late as 158 days in others. No return of voluntary movement was noted in several of the animals immobilized in plaster casts for six months.

The return of faradic response likewise was very inconstant and no conclusions can be drawn from the data on hand. There is a definite need for further study to correlate the return of function with the restoration of muscle and nerve.

CONCLUSIONS

1. Atrophy and degeneration of denervated muscle progress up to a period of at least six weeks despite treatment by passive movement and massage or by electrical stimulation.

TABLE 8.—Correlation of Muscle Restoration with Nerve Regeneration

Six months after sciatic nerve section and suture (no rest preceding treatment)

Treatment	Mon-key No.	Muscle Atrophy	Regenerated Branches to Gastrocnemius-Soleus Muscle		Return of Voluntary Movement (No. of Days)	Return of Faradic Response (No. of Days)
			Total No. of Fibers	Maturity of Fibers		
Electrical stimulation	36	57%	11,170	Mature	122	105
	37	54%	5,920	Immature	118	112
Passive movement and massage	38	37%	8,120	Mature	95	105
	39	30%	8,369	Medium	96	105
Immobilization	42	66%	12,480	Mature	146	No response
	43	61%	8,340	Immature	146	105
Combined electrical stimulation and passive movement and massage	40	53%	11,780	Immature	120	105
	41	Died				
No treatment	44	33%	5,800	Medium	132	105
	45	33%	8,050	Medium	132	105
			Total fibers in normal varied from 11,000 to 21,000			

2. Regeneration and restoration of skeletal muscle, previously denervated, occurs with reinnervation. Unless hindered by excessive fibrosis (prolonged immobilization) or damage to the muscle parenchyma, a good recovery of muscle bulk can be expected.

3. Regeneration of the peripheral nerve occurs at a fairly constant rate. At the end of three months the number of regenerated fibers reaches 60 per cent of the normal. At the end of six months, regeneration of the nerve fibers reaches 80 per cent.

6. Davenport, H. A.; Chor, Herman, and Cleveland, D.: Fiber Ratios in Regenerating Nerves: II. The Status of Regrowth of the Sciatic and Nerves to the Gastrocnemius in Macacus Three Months After Section. *J. Comp. Neurol.* 70: 153 (Feb.) 1939.

7. Davenport, H. A.; Chor, Herman, and Dolkart, R. E.: The Ratio of Myelinated to Unmyelinated Fibers in Regenerated Sciatic Nerves of Macacus Rhesus. *J. Comp. Neurol.* 67: 483 (Oct.) 1937.

4. The degree of regeneration of the peripheral nerve is not (actually) influenced by the use of physical therapy measures.

5. There is no direct correlation between the number of regenerated nerve fibers and the restoration of muscle. It would appear, however, that for regeneration of muscle a minimal number of regenerated nerve fibers must be present.

6. The condition of the remaining muscle is the important factor in determining the degree of muscle repair and recovery which follows the regeneration of the peripheral nerve. In the restoration of muscle, physical therapy is of value. Massage and passive movement therapy appear to be the most beneficial. A preliminary rest period of four weeks before treatment gives uniformly better results than obtained when treatment is given immediately following nerve section and suture. During this rest period the paralyzed muscles should be splinted in neutral position.

7. Further studies are needed to correlate the restoration of function with the return of muscle bulk in order to establish more definitely the effects of physical therapy measures.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

OXYGEN.—"Oxygen contains not less than 99 per cent by volume of O. For convenience it is supplied in compressed form in metallic cylinders." U. S. P.

Actions and Uses.—Oxygen is administered for the purpose of relieving difficult respiration in cases of mechanical hindrance to the ingress of air to the lungs and in the treatment of carbon monoxide poisoning. It is also mixed with nitrogen monoxide when this gas is used as an anesthetic. Oxygen containing from 5 to 7 per cent of carbon dioxide is useful for resuscitation.

OXYGEN-CARBON DIOXIDE MIXTURE.—A mixture in various proportions of carbon dioxide and oxygen.

For standards see U. S. Pharmacopeia under Carbonic Dioxide and Oxygenium.

Caution: The usual precautions concerning use of oxygen apparatus must be followed. Special precaution must be observed against use of oil on valves.

Actions and Uses.—Oxygen-carbon dioxide mixture in varying proportions for supplying artificial respiration and as a stimulant to the respiratory center.

Manufactured by the Denver Oxygen Company, Denver, Colorado. No U. S. patent or trademark.

Oxygen-Carbon Dioxide Mixture, Carbon Dioxide 5%; Oxygen 95%.
Oxygen-Carbon Dioxide Mixture, Carbon Dioxide 7%; Oxygen 93%.
Oxygen-Carbon Dioxide Mixture, Carbon Dioxide 10%; Oxygen 90%.

FUADIN.—Stibophen.—Sodium-Antimony III bis-catechol-2,4 disulfonate of sodium $[(\text{NaO}_2\text{S})_2\text{C}_6\text{H}_2(\text{O})_2\text{:Sb.O.C}_6\text{H}_3\text{O.Na}(\text{SO}_3\text{Na})_2]_7\text{H}_2\text{O}$. It contains 13.6 per cent of trivalent antimony.

Actions and Uses.—Fuadin is proposed for use in the treatment of granuloma venereum and of schistosomiasis (bilharziasis). Its action is reported to be more rapid and efficient in early granuloma venereum than in the later stages when there is scar formation. It is necessary to keep the treatment up for some time after all evidence of the disease has disappeared. In schistosomiasis it is indicated together with iron as the treatment of choice in the intestinal stage of the disease. The iron salts should be given after the completion of the treatment and not concurrently. The anemia, when present, is apparently due to a prolonged iron deficiency.

Dosage.—Intramuscularly (rarely intravenously), first day 1.5 cc., second day 3.5 cc., and on the third, fifth, seventh, ninth, eleventh, thirteenth and fifteenth days 5 cc., a total of 40 cc. of

the 6.3 per cent solution. Following healing in a week or two weeks the course may be repeated and thereafter the drug is given once a week and then every fourteen days for several weeks to prevent relapse.

Manufactured by Winthrop Chemical Co., Inc., New York. U. S. patent 1,549,154 (Aug. 11, 1925; expires 1942) and 1,873,668 (Aug. 23, 1932; expires 1949). U. S. trademark 304,950.

Ampoules Solution Fuadin, 3.5 cc.: Each ampule contains fuadin 0.22 Gm. ($3\frac{1}{2}$ grains); sodium bisulfite, not more than 0.125 per cent.

Ampoules Solution Fuadin, 5 cc.: Each ampule contains fuadin 0.32 Gm. (5 grains); sodium bisulfite, not more than 0.125 per cent.

Fuadin is supplied only in an approximately 6.3 per cent solution with not more than 0.125 per cent sodium bisulfite as a preservative. The solution is clear, odorless and nearly colorless; it possesses a slightly saline taste and acquires a faint pink color on standing in the light. The specific gravity of fuadin solution is not less than 1.037 nor more than 1.041 at 25 C.

To 2 cc. of solution add 0.5 cc. of diluted hydrochloric acid, 10 cc. of distilled water and 1 cc. of sodium sulfide solution: a reddish orange precipitate appears. Dilute 1 drop of fuadin solution to 3 cc. and add one drop of ferric chloride solution: a deep bluish green color appears, which turns brownish red on the addition of ammonia water. To one drop of the solution add 1 cc. of distilled water and one drop of mercurous nitrate solution: a black precipitate appears.

To 1 cc. of fuadin solution, add 2 cc. of a solution of magnesium uranyl acetate: a yellow crystalline precipitate appears. To 1 cc. of the solution add 2 drops of diluted nitric acid and 2 drops of silver nitrate solution: no opalescence is produced immediately (chloride).

To 2 cc. of fuadin solution add 20 cc. of bromine water and 1 cc. of diluted hydrochloric acid; expel the bromine by boiling and add 1 cc. of ammonium thiocyanate solution: no red color appears (iron). To 2 cc. of fuadin solution add 1 cc. of ammonium hydroxide and 2 drops of ammonium oxalate solution: no precipitate appears (calcium).

To 2 cc. of fuadin solution in a glass stoppered flask, add 2 cc. of diluted acetic acid and 0.6 cc. of formaldehyde solution and allow to stand five minutes. Add an excess of fiftieth-normal iodine solution and, after five minutes, titrate the excess with fiftieth-normal sodium thiosulfate, using a 1 per cent starch solution as indicator: the trivalent antimony content is not less than 0.81 nor more than 0.88 Gm. per hundred cubic centimeters.

Transfer 5 cc. of fuadin solution to a 250 cc. beaker and add 18 cc. of diluted hydrochloric acid and 32 cc. of water. Evaporate the solution to about 5 cc. and neutralize with sodium hydroxide solution. Transfer to a nickel crucible, evaporate to dryness and add 3 Gm. of sodium hydroxide containing 5 per cent potassium nitrate. Fuse the mixture and heat until it is free from organic matter and dissolve the cooled melt in 100 cc. of water. Acidify the solution with diluted hydrochloric acid, add 1 Gm. of tartaric acid, filter, and precipitate the sulfates by adding 5 cc. of a 10 per cent barium chloride solution. Digest on a steam bath for at least three hours, filter on a Gooch crucible, ignite and weigh: the sulfur content is not less than 0.847 and not more than 0.950 Gm. per hundred cubic centimeters.

BISMUTH SUBSALICYLATE (See New and Nonofficial Remedies, 1939, p. 141).

The following dosage forms have been accepted:

Bismuth Subsalsicylate in Oil (Gilliland), 0.13 Gm. (2 grains) per cc.: A suspension of bismuth subsalsicylate in vegetable oil containing in each cubic centimeter 0.13 Gm. (2 grains) of bismuth subsalsicylate U. S. P. with 3 per cent of chlorobutanol added. Marketed in vials containing 15 cc., 30 cc., 60 cc. and 120 cc. and in bottles containing 480 cc.

Prepared by Gilliland Laboratories, Inc., Marietta, Pa. No U. S. patent or trademark.

Bismuth Subsalsicylate in Oil (Gilliland), 0.2 Gm. (3 grains) per cc.: A suspension of bismuth subsalsicylate U. S. P. in vegetable oil containing in each cubic centimeter 0.2 Gm. (3 grains) of bismuth subsalsicylate with 3 per cent of chlorobutanol added. Marketed in vials containing 15 cc., 30 cc., 60 cc. and 120 cc. and in bottles containing 480 cc.

Prepared by Gilliland Laboratories, Inc., Marietta, Pa. No U. S. patent or trademark.

DIGITALIS (See New and Nonofficial Remedies, 1939, p. 183).

The following dosage forms have been accepted:

Capsules Digitalis Powder, 1 grain ($\frac{1}{2}$ U. S. P. Digitalis Unit): Dispensed in blue capsules.

Prepared by The Maltbie Chemical Company, Newark, N. J.

Capsules Digitalis Powder, 1½ grains (1 U. S. P. Digitalis Unit): Dispensed in blue capsules.

Prepared by The Maltbie Chemical Company, Newark, N. J.

SULFARSPHENAMINE - MALLINCKRODT (See New and Nonofficial Remedies, 1939, p. 100).

The following dosage forms have been accepted:

Sulfarsphenamine-Mallinckrodt, 0.9 Gm. Ampoules.
Sulfarsphenamine-Mallinckrodt, 3.0 Gm. Ampoules.

RABIES VACCINE (See New and Nonofficial Remedies, 1939, p. 414).

The Gilliland Laboratories, Inc., Marietta, Pa.

Rabies Vaccine-Gilliland (Modified Semple Method).—An antirabic vaccine that differs from Rabies Vaccine-Gilliland (Semple Method) in the concentration of virus, in the period of inactivation and in the dose to be administered. The vaccine consists of brain and cord tissue removed from rabbits killed after being completely paralyzed following an inoculation of fixed rabies virus. The brains and cords are emulsified in the presence of a 1 per cent phenolized physiologic solution of sodium chloride to make a 40 per cent emulsion. The mixture is incubated at 36.5 C. for a sufficient time to inactivate the virus. The usual safety tests are applied on the 40 per cent virus tissue emulsion. The product is then further diluted, after completion of safety tests, with an equal volume of physiologic solution of sodium chloride so as to contain 20 per cent of the brain and cord substance. Marketed in packages of fourteen vials, each containing 0.5 cc.

Dosage.—The content of a syringe or vial is administered daily over a period of fourteen days.

TIN, TAPEWORMS AND TUSH

Recently physicians have received a circular recommending the use of a tin compound called Stannoxyll as a teniafuge. The circular, entitled "Exit Tapeworm," was circulated by the Anglo-French Drug Co., Inc., New York City, and promised "Tapeworms Expelled Without Fasting or Purging." Stannoxyll is also recommended for the treatment of "boils and styes," and has been so advertised by the firm for some time. Published evidence to sustain these contentions is not available either in amount or in quality.¹ Kolmer and Harkins² have reported on "Stannoxyll in the Chemotherapy of Experimental Staphylococcus Infections." They concluded that the drug was of low toxicity in rats and rabbits by oral and intramuscular administration but was without demonstrable therapeutic effect on experimental subcutaneous abscesses of guinea pigs and without similar effect on abscesses of the internal organs of rabbits. A further note by Kolmer, Brown and Harkins³ on tin compounds in the chemotherapy of experimental staphylococcic infections confirmed their earlier views.

Now Stannoxyll is recommended as a teniafuge, in addition to its use "for boils and styes." In the circular the firm states that "Numerous Canadian and French physicians have used Stannoxyll, the original combination of metallic tin and tin oxide, and report that it seldom fails to expel *Tenia Saginata* within twenty-four hours." The *Quarterly Cumulative Index Medicus* reveals only one such report by Lepinay,⁴ a veterinarian, describing the use of tin salts as a teniafuge for teniasis in dogs. He reports only one case of its use in a human being. After recounting the difficulty of determining whether or not the heads of the worms had been passed by either the dogs or the human being, he concludes

with a statement (translated): "The salts of tin appear to be a treatment of choice for teniasis as much from the point of view of rapidity of action as from the ease of absorption." Such a conclusion is obviously unwarranted on the basis of the evidence presented. No bibliography is appended to the report.

Yet in the circular concerning Stannoxyll the firm states that "The discovery of its specific value for tapeworms was made accidentally by Lepinay in 1933. . . . He observed that many of his patients, while taking Stannoxyll Tablets for boils, passed tapeworms during the course of the treatment." Apparently the firm draws no distinction between dogs and man in speaking of a veterinarian's patients. Actually Lepinay reported success in expulsion of the tenia from one human being in the course of two days' treatment, whereas the firm claims that Stannoxyll was reported to fail seldom in the expulsion of *Taenia saginata* within twenty-four hours. The firm uses only the one reference, for the good reason that there appear to be no others on this subject in the literature. Even this might be excusable if the report constituted scientific evidence and was cited accurately, without gross oversight of the facts.

TRANSPLANTATION OF ADRENAL CORTEX FOR ADDISON'S DISEASE

The feasibility of successful transplantation of the adrenal gland in animals has been demonstrated by a number of investigators. The rat, according to Jaffe,¹ offers excellent opportunities for such a study. In his experience successful transplants were obtained in at least 80 per cent of attempts. The process of regeneration was completed in from three to four weeks, after which time the transplant grew and reached the size of a normal gland. Jaffe and Plavska's autoplasic transplants in guinea pigs maintained their animals for months after the removal of the second main gland. These results appear to be conclusive of function when the results are compared with the results for guinea pigs whose adrenals were removed and in which transplants were not done; these survived three or four days. Elliott and Tuckett² observed that the subcutaneous tissues of guinea pigs are peculiarly sensitive to adrenal grafts, which produce in them edema and hemorrhagic dissolution. Their investigations proved that the irritant substance occurs entirely in the medulla of the gland. However, even in this animal, if only the cortex is transplanted, a large percentage of takes is obtained. Jaffe and Plavska found that by separating the cortex from the medulla and dividing the cortex into small fragments and washing them thoroughly in sterile physiological solution of sodium chloride it was possible to

transplant these into the rectus muscle of the guinea pig and obtain a high percentage of takes.

The same authors found in sixty-three of sixty-seven rats in which the transplants were large and well vascularized and in which necropsy showed the absence of accessories that the animals approached the normal litter and sex controls in weight and activity and withstood doses of vaccine that invariably killed adrenalectomized rats that had not received transplants.

In 1922 Hurst, Tanner and Osman³ reported a case of a male who presented himself with a typical picture of advanced Addison's disease. Administration of large doses of adrenal extracts and of hydrochloric acid by mouth and the injection of 1:1,000 epinephrine did not cause any obvious improvement. An adrenal gland removed from a man who had just died was grafted into the subcutaneous tissues in the inguinal region of the patient. Two weeks later an adrenal removed from a fetus just after death was grafted into the recipient's left testicle. There was slow improvement and a rise in blood pressure from 75 to 95. Nine months later the patient felt well. His systolic blood pressure had risen to 115.

Currie⁴ in 1924 transplanted an adrenal gland of a sheep into an abdominal incision of a moribund patient. Four days later the patient was better, the blood pressure having risen from 70 to 110. Nine days later the transplant showed signs of suppuration and the patient relapsed. A second transplantation of both adrenals of a sheep was performed the following day. The adrenals were cut into fine strips, washed in warm saline solution and placed in the barrel of a 10 cc. syringe with a wide bone needle. The needle was inserted into the subcutaneous tissues of the patient on each side of the abdomen and the tissues forced out as the needle was withdrawn. Two months later the patient was much improved and her blood pressure was 100/75. Reinhart⁵ transplanted in 1928 the adrenal taken from a patient with tuberculosis of the kidney at the time of operation into the abdominal wall of a patient in an advanced stage of Addison's disease. There was an immediate improvement, the blood pressure gradually rising from 85 to 125. The patient was apparently in good condition six months after the transplantation. The author emphasized two interesting facts: a marked scaling of the skin and the onset of menstruation eight days after the transplantation in a patient who had had amenorrhea for a long time. Frank d'Abreu⁶ in 1933 transplanted into a patient presenting symptoms of advanced Addison's disease adrenal glands from a patient who had just died. The patient's systolic blood pressure rose from 40 to 76 in the course of

the next few days. Eleven days after the first transplant an adrenal gland of a recently dead newborn infant was transplanted into the abdominal wall of the patient. There was but little improvement, the patient dying nine days later. Postmortem revealed that both grafts had suppurated.

The fact that the medulla of the gland was responsible for the rapid necrosis and suppuration was apparently not appreciated by the clinicians. Beer and Oppenheimer⁷ were first, in 1934, to transplant the adrenal cortex alone. They removed the adrenal from a patient in the course of an operation on the kidney, stripped it of the medulla and implanted it in small pieces into avascular pockets made in the recipient's rectus muscle. Their first patient showed temporary improvement but died fourteen days later of a progressive infection starting in a bed sore. The microscopic examination demonstrated that the bits of adrenal cortical transplants maintained their structure and were apparently viable. A rather striking success was obtained in the second patient, in whom transplantation was made while he was in a state of stupor. A few weeks later a second transplantation was performed. This patient apparently made a complete recovery. The authors suggest the combined use of adrenal cortical transplantation and of Collip's adrenotropic fraction of anterior pituitary gland extract to stimulate the transplant and whatever viable adrenal rests the host may possess.

Auslender⁸ reports fourteen cases of Addison's disease in which heterotransplants were employed. The adrenal was removed immediately on the killing of the animal at the abattoir, and the cortex was dissected from the medulla in the operating room. Fragments of the cortex were implanted in the subcutaneous tissues of the abdomen. The immediate results were excellent in all fourteen cases, an increase occurring in weight, muscle power, blood pressure, blood cholesterol and blood sugar. Nausea, vomiting, diarrhea and achylia disappeared. More or less permanent results were obtained in the mild cases. The longest case was observed for a year and eight months. In a few cases the improvement was progressive. In the severe cases the improvement lasted from five to six months, after which there was a gradual return of the symptoms, necessitating a second transplantation in from nine to twelve months. The results after the second transplantation were equally good.

In view of the outlook in Addison's disease and the frequent failure of replacement therapy, the homotransplantation and heterotransplantation of the adrenal cortex seem to offer some hope of amelioration and to justify further trial.

Current Comment

WEATHER CONDITIONS AND ASTHMA

The possibilities of experimental meteorobiologic research are well illustrated by Preuner's¹ report of the effect of weather conditions on experimental asthma in guinea pigs. The earlier methods of producing anaphylactic shock in guinea pigs produced allergic syndromes and sequelae rarely encountered in human medicine. Most immunologists were skeptical therefore of the clinical applicability of conclusions drawn from animal experimentation. Alexander² and others demonstrated, however, that a symptom complex identical with that of human asthma can be produced in this animal species by allowing highly sensitized guinea pigs to breathe "vaporized antigens," i. e. invisible sprays of foreign proteins. Apparatus for the administration of such antigenic "vapors" were subsequently perfected by European investigators.³ Guinea pigs previously sensitized by a single intraperitoneal injection with 0.1 cc. of egg white, for example, were allowed to breathe a fine egg albumin "vapor," the apparatus being adjusted so that each invisible spray droplet was less than 5 microns in diameter. Coarser sprays were found to be less effective. Distinct asthmatic symptoms are usually noted within two minutes after the beginning of this "vaporization" test, increasing in severity till the tenth minute. If death results, the animals exhibit at necropsy the classic appearances of acute anaphylactic shock. By varying the richness of the spray and by recording from minute to minute the severity of the asthmatic attack and using a sufficiently larger group of animals, a statistically reliable mathematical expression of the average group severity was found possible. Thus, in one group of eight guinea pigs tested by a low vapor concentration a borderline asthmatic reaction (grade 1.5) was noted during the second minute, increasing to grade 2.9 by the fourth minute, with grade 3.3 symptoms by the end of eight minutes. Beginning clonic convulsions (grade 4) were noted in two guinea pigs of this series. Preuner found that lethal asthma (grade 6) was not produced by the dilute spray selected from this group. On convalescence from the asthmatic attack, guinea pigs are found not to have been desensitized and to react over and over with the same mathematical index. Applying this statistical index to large groups of animals, Preuner found that the statistical severity of "vapor" asthma is not dependent on such meteorological factors as temperature, humidity or atmospheric pressure as long as these factors remain constant on the day of the experiment. During periods of rapid changes in weather conditions, however, the average severity is increased about 50 per cent. Thus, in one group of animals tested and retested over a long period the average severity on a dilute spray mixture was only 1.5 on calm days, increasing to an average of 2.2 on days of rapid

meteorological change. While this result would seem to be merely confirmation of a popular clinical belief, the fact that meteorological factors are thus subject to accurate statistical study in laboratory animals is of basic scientific interest. The new field of experimental meteorobiology may conceivably assume an important role in future therapeutic study.

TESTS FOR ATHLETIC EFFICIENCY

Physical fitness and athletic efficiency, according to Abrahams,¹ are by no means the same thing. Fitness he conceives as satisfactory adjustment to one's environment as used in the widest sense. Thus, for example, a man may be fit to climb a mountain and yet unfit for the strain of city life. For practical purposes the comparatively simple methods in common use to estimate the physical efficiency of the healthy athlete are, he believes, probably as satisfactory as the more elaborate investigations, which are after all only extensions of fundamental principles. He presents some interesting observations in the same individuals on the rate of deceleration of the pulse after running varying distances, indicating that delayed deceleration is related to duration of exercise which in some way probably leads to a block of vagus inhibition. Concerning the superathlete, Abrahams' remarks warrant quotation: "It is natural to desire to identify some factor which makes for supremacy; it is only to be expected, however, that any such search will be disappointing. After all, although the objective superiority on the track of the superman (the Olympic champion) over the generally accepted 'first-class' athlete is very striking, numerically considered it amounts to only perhaps 4 per cent. Such a difference, if depending on anatomical conformation making for better leverage, would be outside the range of accurate measurement; furthermore, the difference might be some tiny superiority in muscle chemistry or other biochemical factor. When all is said and done, it is a question of coordination of all the various factors working in harmony. Even so mechanical a structure as a motor engine presents the same problem: the perfect chassis is produced when all the parts concerned in locomotion are exactly right at the right moment. And when, as in the case of the human machine, vital phenomena are added, it is not remarkable that no one outstanding criterion can be identified." Athletic efficiency is usually tested by the response of the circulation to effort or to other factors influencing cardiac acceleration or blood pressure. Every test, Abrahams concludes, involving blood pressure is fallacious because of the emotional factor. The rate of cardiac deceleration, however, after a short intense effort, is a valuable index of athletic fitness. Ordinary tests for the effect of prolonged effort are, however, unpractical and he suggests that running various distances by the same individual and observing the rate of cardiac deceleration furnish a more satisfactory method.

ORGANIZATION SECTION

LOST PATIENTS FROM AN OUTPATIENT CLINIC

A STUDY IN COOPERATIVENESS OF PATIENTS

HORACE GRAY, M.D., AND MARGARET CURTIS, R.N.
SAN FRANCISCO

In these days of agitation over adequate medical care it is no less than just to insist that, within the economic level locally accepted in outpatient clinics, medical care be both expert (so far as humanly possible in a grade A medical school today) and extremely cheap to the patient (at a generous financial deficit to the university) and by contrast to analyze the willingness of patients to avail themselves of their opportunities. The present evidence is based on outpatients but probably holds also for many private patients.

From this clinic evidence has been published to the effect that (1) among patients with diabetes who missed

TABLE 1.—Failed Appointments

	Diabetic	Endo- crine	Total
Appointments kept	1,862	977	2,839
Appointments failed	291	186	477
Appointments kept plus failed, total.....	2,153	1,163	3,316
Appointments failed in percentage of total appointments made	11	16	14

appointments the proportion of those presumably recoverable but not recovered amounted to the discouraging value of 55 per cent¹ and (2) among patients with obesity treated in the same clinic by the same staff, thus equalizing the personal equation as a factor, the number of patients abandoning treatment within one month was seventy-one, while the later loss for non-cooperation was thirty-one, making a total wastage of 102 patients, which was 32 per cent of the 314 records sifted.²

RESULTS OF OBSERVATIONS

In the desire to improve our results it was decided for the calendar year 1938 to pursue our follow-ups systematically at a shorter interval, namely one month. The outcome is examined in this paper.

Follow-Up Steps.—1. When a patient failed to come in, our practice has been as follows: A post card was sent out, giving a new appointment in a week. 2. If the patient did not then return, a second card was sent. 3. If the patient failed to return or report after the two cards, the nurse in the clinic made a home visit. The results of these three steps may now be examined in turn.

Number of Patients Followed Up.—The number of persons who failed to return and therefore were followed up was about equally divided between the two main groups of our patients: diabetes (with or without

some obesity) 132, or 52 per cent; endocrine (mostly obesity) 122, or 48 per cent; total 254, or 100 per cent.

Number of Failed Appointments.—Of the total 254 patients, furthermore, nearly half (45 per cent) missed their appointments more than once in the year; i. e. those who failed once were apt to fail repeatedly. Accordingly, taking this larger number of "fails" rather than patients as the major item, we find that the total number was 477 fails. This is divisible as shown in table 1.

Frequency of Failed Appointments per Patient Annually.—Although both disease groups were given appointments at about the same intervals and, according to the preceding paragraphs, contained about equal numbers of patients and also an equal percentages of fails, these figures do not reveal all. In fact the diabetic seemed more careless, averaging 2.2 fails per patient but the endocrine only 1.5 fails per patient (table 2).

These high fails of 2.2 per diabetic patient are due to the fact that, while no obese patient failed more than four times, some diabetic patients failed five, six, or even seven times. This is shown by splitting down the last table into number of patients concerned and frequency of fails per patient; then multiplying the frequency of fails by the number of patients in each column and adding 1×141 plus 2×55 and so on we find the total number of fails and also the percentage frequency in each column for that degree of carelessness (table 3).

Economic Level.—Ponteva³ found 45 per cent of 266 diabetic patients analyzed who gave up the diet and the cause was poverty in 47 per cent of these, i. e. 21 per cent of the total; hence the high diabetic death

TABLE 2.—Failed Appointments Per Patient

	Diabetic	Endocrine	Total
Fails.....	291	186	477
Patients.....	132	122	254
Fails per patient.....	2.2	1.5	1.9

rate in Finland. Similarly in the present series the highest proportion of the failing patients belonged to the lowest economic level C, i. e. 45 per cent of the failing diabetic and 38 per cent of the failing endocrine patients. Curiously enough the lowest proportion was accounted for not by the best economic level (A) but by the middle level (B), both among the diabetic and among the obese.

If we consider the average frequency of fails according to economic class, the results are not clearcut, being worse for level C (as expected) among the obese, but among the diabetic for level B (not C) as shown in table 4.

From the Medical Clinic, Stanford University School of Medicine. The authors were helped by Mrs. Ena Backus and Mrs. Florence Stevens. Financial support was given by the Diabetic Research Fund contributed by an anonymous donor.

3. Ponteva, Eero: Ueber die Resultate der Diabetesbehandlung in Finnland, Acta med. Scandinav., supp. 88, 1938.

Failing Patients Sent Postcards.—The average number of postcards sent out per failing patient may be counted thus: diabetic, 398 to 132 patients, averaging 3 cards each; endocrine, 256 to 122 patients, averaging 2.1 cards each; total, 654 to 254 patients, averaging 2.6 cards each.

The 654 cards may also be divided as follows: returned after one card, 300 patients (300 cards); returned after two cards, eighty-three patients (166 cards); not returned after two cards plus telephone, thirteen patients (twenty-six cards); remainder needing home visits, eighty-one patients, 162.

Proportion of Failed Appointments Recovered by Postcard.—More instructive though more elaborate is the analysis of the proportion of failed appointments made good by postcards. We found that 63 per cent of the fails were remedied by one postcard, another 17 per cent by the second card, 3 per cent accounted for by telephone, and 17 per cent required home visits to get them back (table 5).

Reported (by Telephone) But Didn't Return.—Attempts were made in this way to keep contact with some patients who failed to answer cards, but the number of patients reached was so small (thirteen) that the method appears useless. The results were: moved out of town, two; to other medical care, two; promised to return but failed, nine; recovered, none.

Home Visits.—So we finally had left eighty-one failed appointments needing approach by home visits. This method succeeded in twenty-two out of eighty-one, or 27 per cent. The residual fifty-nine utter losses are shown in table 6 (i. e. 12 per cent of all 477 failed appointments).

SUMMARY

"Clinic fails," i. e. missed appointments to return to the clinic the day agreed, were studied for the calendar year 1938. There were 254 failing patients having 477 missed appointments, which amounted to 14 per cent of the appointments made. The number of these fails which despite our best efforts could not be recovered amounted to 17 per cent of all the missed appointments. Diabetic patients seemed more negligent than the obese.

These results are most discouraging from the point of view of social economy, the time spent on them by

the admitting office, clinical clerk, nurse, dietitian, physicians and social worker. Constructively, for the good of the greatest possible number of patients, particularly in connection with controversies about the best form of social health insurance, our results strongly indicate

that first-visit patients (unless seriously sick) should be treated rather rapidly, which incidentally would save time for them also. This will spare the time of the clinic staff, time which seems likely to be better spent on such second-visit patients as exhaustive and therefore expensive (for some one if not for the patient) examination.

HOW CAN YOU MAKE THEM TAKE IT?

Statistics of smallpox offer clinching evidence that something besides poverty and inaccessibility accounts for failure to receive needed medical service. It is more than a century since vaccination has been proved to constitute complete protection against a deadly and disfiguring disease, and it is available almost everywhere at little or no expense. Yet the United States Public Health Service in *Public Health Reports* 54:1091 (June 23) 1939 says "The United States led all other nations of the world except India in the number of smallpox cases reported in 1937."

Only neglect of vaccination causes smallpox to find thousands of victims in some sections of the country and none at all in others. "New Jersey, with a population of about 4,400,000, has not had a case for more than seven years, while the states of North Dakota, South Dakota, Montana, Idaho, Oregon, Wyoming and Utah, with a combined population less than that of New Jersey, reported during the same period a total of more than 12,000 cases. . . . One of the explanations—not excuses—is probably the comparative mildness of the disease in recent years." But there is "always the danger that the malignant form may be introduced from outside our boundaries." That is just what appeared in one Western state where vaccination had been neglected. "Within twenty months 4,021 cases of the malignant disease occurred, taking over 500 lives."

HYGEIA LOAN COLLECTIONS

An important phase of the doctor's duty in the prevention of disease is the education of the public. One of the most effective mediums is the platform speaker, the personal appearance of the doctor before the lay audience. The Bureau of Health Education of the American Medical Association has made help available to the physician-speaker by furnishing him loan material from which he can prepare a paper or address on health suitable for a nonmedical audience. The material consists of *Hygeia* articles bound in a folder and accompanied by an outline. In 1936 the service began to be used by an increasing number of physicians.¹ There were 226 requests. It is operated on almost the same basis as the Package Library of the American Medical Association. In 1937 there were 375 requests, including

ing a loan collection service of this type in obtaining the material at the lowest possible cost.

It is difficult, if not actually impossible, to have enough collections on all the topics available to supply the many physicians who may request a particular subject at the same time. Although the Bureau has developed seventy-nine topics and has as many as twenty-two copies available on some of the more popular subjects, it is advisable for the speaker to name a second and third choice when ordering. In this way the physician is assured of receiving material on one of the subjects which he proposes to discuss. These collections are revised frequently and kept up to date by the addition of newly published material. New subjects are constantly being added and those which appear to be of

three from Honolulu. In 1938 the demand for these collections more than doubled.² The accompanying maps for 1937 and 1938 show the distribution of requests for this material. The map for 1938 includes many foreign requests: Canada, China, Canal Zone, Puerto Rico and Alaska. During 1939 the demand for these collections has kept up and for the first six months 361 requests were received and filled. Collections have been sent to physicians in all states but one.

The New Jersey Medical Society and the Westchester County Medical Society of New York have developed speakers' services of their own. The Bureau aided these societies in obtaining material by sending them the back issues of *Hygeia*, the Health Magazine, in which the many articles used in the collections have appeared. This development makes it possible for physicians in those states to receive collected material directly from their local and state societies. The Bureau of Health Education will aid other societies desirous of establish-

ing a loan collection service of this type in obtaining the material at the lowest possible cost.

The following rules have been made with regard to the lending of this material:

These clipping collections are available to any one preparing a paper or address on health for a lay audience. Only one collection may be borrowed at a time and it must be returned within ten days mailed flat. A return envelop will be furnished, on the flap of which will be penciled the amount of postage required to mail the material back to us. The material goes as third-class mail; the postage rate is one and one-half cents for two ounces.

Collections should be ordered by number and a second and third choice of subjects indicated. We will endeavor to send the first choice, but it may not be possible, owing to the great demand for these collections and the limited number available on a given subject. Cooperation in returning this material promptly will be appreciated. Make requests at least two weeks before a scheduled address.

The county and state societies, through their speakers' bureau can well afford to offer the services of

1. Teschner, Paul A.: Doctors and Public Speaking. A. M. A. Bull. 31: 131 (June) 1936.

2. Teschner, Paul A.: When Doctors Address the Public. J. A. M. A. 110: 155B (March 19) 1938.

physician speakers to the many groups that have regularly scheduled meetings in each community. Groups such as Parent Teachers Associations, women's clubs, service clubs such as Rotary, Kiwanis, Optimists, American Legion, church organizations and auxiliaries, and many other societies offer excellent opportunities for speakers. Not to be forgotten are the high schools

and secondary schools found in each community. Through the schools, the physician will find opportunity to speak to various youth organizations such as the Boy and Girl Scouts and the 4-H Clubs. This group is ever eager for information that the physician has to offer. The dissemination of health knowledge must be repeated year after year as new groups replace the old.

Distribution of loan collection material in 1937.

Distribution of loan collection material in 1938.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARKANSAS

Society News.—At the annual joint meeting and picnic of the Benton-Washington Counties Medical Society at Bentonville July 13 the speakers were Drs. Joy K. Donaldson, Little Rock, on "Improved Management of Appendicitis"; Merlin J. Kilbury, Little Rock, "Laboratory Findings in Appendicitis"; Felix A. Hughes Jr., Prescott, "Diverticula of the Gastrointestinal Tract," and Albert S. Buchanan, Prescott, an analysis of the Wagner Bill.

New Director of Venereal Disease Control.—Dr. Donald W. Dykstra, Morrilton, has been appointed in charge of the new syphilis control division of the state department of health, newspapers announced recently. He will assist Dr. Arthur M. Washburn, Little Rock, director of the division of communicable disease control. Another member of the new division will be Dr. Arthur B. Price, U. S. Public Health Service, who has been assigned to the state department for a year of field training. The division will undertake a survey of syphilis to determine the prevalence and results of treatment and is expected to launch a mobile venereal disease unit soon.

CALIFORNIA

Child Guidance Clinic at Stanford.—A grant of \$10,000 a year for three years to Stanford University School of Medicine, San Francisco, by the Commonwealth Fund of New York has been announced, to finance a child guidance clinic under the joint direction of the departments of psychiatry and pediatrics. The new clinic will be an expansion of the present work on behavior problems and will provide opportunities for graduate and undergraduate training of physicians in this field. Dr. Ray Lyman Wilbur, president of the university, also announced acceptance of a gift of \$200,000 from the Rockefeller Foundation for research in biologic sciences; \$1,000 as a second instalment of a gift of \$2,000 to the medical school for research in epilepsy from the William G. Irwin Charity Foundation, and \$500 from the Sloss family to establish the M. C. Sloss Loan Fund for students.

CONNECTICUT

Society News.—Dr. Emil Novak, Baltimore, discussed "Endocrine Influence of Certain Ovarian Tumors," before a recent meeting of the Bridgeport County Medical Association. —Dr. James L. Gamble, Boston, addressed the Hartford County Medical Society recently on "The Pathogenesis of Dehydration, Acidosis and Alkalosis."

FLORIDA

Personal.—Dr. George R. Creekmore, Brooksville, has been appointed a member of the board of commissioners of Hernando County. —Dr. Leigh F. Robinson, Fort Lauderdale, president, Florida Medical Association, was recently presented with a wrist watch by the Broward County Medical Society as a token of esteem.

New State Health Officer.—Dr. Albert B. McCreary, director of the bureau of county and district health work of the state board of health, Jacksonville, has been appointed state health officer to succeed the late Dr. Wilbur A. McPhaul. Dr. McCreary graduated from the University of Tennessee College of Medicine, Memphis, in 1922 and has engaged in public health work in Tennessee, North Carolina and Virginia. He has been with the Florida board for four years.

GEORGIA

Regional Health Officers Appointed.—In an expanded state health program six regional health units have been established under the supervision of the state department of health. Dr. Bert H. Malone has been appointed regional medical director of the southeastern regional office with headquarters in Waycross. Others are Drs. Robert B. Griffin, northwestern district, Marietta; Aaron Wilson Brown, northeastern district, Gainesville; Rufus Floyd Payne, west central

district, Griffin; John M. Walton, east central district, Swainsboro, and Lester M. Petrie, southwestern district, Albany.

Fourth District Meeting.—At a meeting of the Fourth District Medical Society in LaGrange August 8 local speakers presented papers which were discussed by Atlanta physicians. They included:

Dr. Emery C. Herman, LaGrange, Pneumonia Complicated by Pneumococcal Meningitis Treated with Sulfapyridine. Discussion by Dr. Hugh Wood, Atlanta.

Dr. Kenneth D. Grace, LaGrange, Goiter Complicated by Other Conditions. Discussion by Dr. David Henry Poer, Atlanta.

Drs. Robert P. Morrow, West Point, and Enoch Callaway, LaGrange, Hyperinsulinism Treated by Resection of the Pancreas. Discussion by Dr. Henry C. Sauls, Atlanta.

Dr. James S. Holder, LaGrange, Fractures of the Femur. Discussion by Dr. Thomas P. Goodwyn, Atlanta.

Drs. William H. Myers, Savannah, and Job C. Patterson, Cuthbert, president and president-elect, respectively, of the Medical Association of Georgia, made addresses.

ILLINOIS

Typhoid Epidemic in Manteno State Hospital.—Eleven persons have died of typhoid and about 200 are ill at the Manteno State Hospital, Manteno, the Chicago Tribune reported September 5. Health department investigators have traced the outbreak to artesian wells from which the hospital's drinking water is obtained, but the possibility of a human carrier is also being investigated. All the 5,400 patients and 770 employees are being vaccinated.

Society News.—Drs. Guy M. Cushing and Chauncey C. Maher, Chicago, addressed the Henry County Medical Society, Kewanee, August 24, on "Acute Perforating Gastric and Duodenal Ulcers" and "Cardiorenal Disease with Emphasis on Renal Conditions" respectively. —Dr. Howard A. Lindberg, Chicago, director of the pneumonia serum center for the state department of health, will address the Rock Island County Medical Society September 12 in Moline on the pneumonia control program.

Chicago

Fund for Tuberculosis Survey.—The Julius Rosenwald Fund has made a grant of \$3,000 to the University of Chicago to finance a search for unsuspected cases of tuberculosis among patients of the Provident Hospital Clinic. The fund will provide equipment for fluoroscopic examination of about 30,000 patients during the next year. All patients registered will be examined and the families of all those found to have the disease will also be examined, according to the announcement.

Criteria of Premature Birth.—The Chicago Board of Health recently issued a statement giving criteria of premature birth in order to simplify reporting of premature and immature infants. Physicians and hospitals should report any infant weighing 2,250 Gm. or less at birth and any premature infant, irrespective of weight. The regulations require that any immature infant shall be reported to the health department by telephone within an hour after birth, and the report must be confirmed in writing within twenty-four hours.

Surgical Society Offers Prize.—The Chicago Surgical Society announces that competition for its 1940 annual prize is now open to physicians, not members of the society, devoting themselves to surgery in Cook County. The prize of \$250 will be awarded for the most meritorious original investigation in one or both of the fields of experimental and clinical surgery, which has not been printed or presented previously. The manuscript should bear no identification marks of individual, hospital or institution but should be accompanied by a sealed envelop bearing on the outside the title of the paper and containing within it the name and address of the author. The society reserves the right to make no award if the papers submitted do not have sufficient merit. Manuscripts should be sent to the secretary of the Chicago Surgical Society, 54 East Erie Street, Chicago, not later than March 1, 1940.

KANSAS

Annual Registration Due Between July 1 and October 1.—Physicians licensed to practice medicine in Kansas are required to renew their licenses annually between July 1 and October 1 and to pay a fee of \$1 to the secretary of the board of medical registration and examination. The secretary must strike from the register of licensed physicians the names of all physicians who fail to pay their annual registration fees as required by law. Physicians whose names are so removed may be reinstated by paying the secretary \$5 and submitting to him satisfactory proof of moral fitness.

KENTUCKY

Exhibit at the State Fair.—The University of Louisville School of Medicine is presenting a public exhibition at the state fair in Louisville. Specimens are being taken from the pathology museum and arranged under the direction of Dr. Aura J. Miller, professor and head of the department of pathology and serology in the medical school.

Society News.—Dr. Walter S. Wyatt, Lexington, addressed the Bourbon County Medical Society, Paris, August 17 on "Gastric and Duodenal Ulcers."—Dr. Francis M. Massie, Lexington, addressed the Harrison County Medical Society, Cynthiana, August 7 on "The Ameba as a Cause of Abdominal Pain."—Drs. Lee Palmer and Philip F. Barbour, Louisville, addressed the summer meeting of the Southwest Kentucky Medical Association in Bardwell August 1 on "Sulapyridine in the Treatment of Pneumonia in Children" and "Acute Abdominal Conditions in Children" respectively.—Speakers at a meeting of the Muldraugh Hill Medical Society at the Brown-Pusey House, Elizabethtown, August 10 were Drs. Walter I. Hume and Thomas J. Crice, Louisville, on "Control of Hemorrhage" and "The Psychiatrist's Responsibility to Society and the So-Called Criminally Insane" respectively.—Drs. Burnett W. Wright, Nashville, Tenn., and William R. McCormack, Bowling Green, addressed the Third District Medical Society in Bowling Green July 19 on "Stones in the Upper Urinary Tract" and "Management of Breech Deliveries and Placenta Praevia" respectively.

MAINE

New State Health Officer.—Dr. Roscoe L. Mitchell, assistant director of the bureau of health in the state department of health and welfare, has been appointed director to succeed Dr. George H. Coombs, who resigned. Dr. Mitchell graduated from the University of Vermont College of Medicine, Burlington, in 1908.

MARYLAND

Personal.—Dr. Robert H. Riley, Baltimore, state health officer, was given a testimonial banquet July 5 in celebration of his completion of twenty-five years on the staff of the department.—Dr. Frank B. Hines, Chestertown, has been named deputy medical examiner for Kent County by the newly created Maryland Postmortem Examiners' Commission, it is reported.

Bacteriologist Dies.—Dr. Otto Wolfgang Wichelhausen, assistant in bacteriology at Johns Hopkins University School of Medicine, Baltimore, since 1937, died suddenly at Bar Harbor, Maine, August 14, aged 35. Dr. Wichelhausen took his medical degree from the University of Goettingen in 1933 and held degrees from the University of Düsseldorf and the Hamburg Institut für Schiffahrts und Tropenhygiene. He had conducted research on anaphylaxis in guinea pigs with plant antigens, sulfanilamide in experimental streptococcal infections and oral infections.
